 these suggestions for help in a difficult diagnostic problem.
 In a dweller in the Alps with this infection there will be found some
 of these conditions. A tumour of the liver with no evidence of another
 to which it could be secondary. Deep jaundice with comparatively
 slight subjective troubles good appetite no cachexia eosinophilia an
 X ray plate shows calcification and there is an unusually long history.
 In this way an explanatory laparotomy will not leave the condition
 labelled as cancer of the liver with undiscovered primary focus
 Only histological examination can give a right diagnosis.
 C L.

CHUNG (Huei-Lan) & TUNG (Tsun) The Non-Specificity of the
 So-called Specific Biological Tests for Hydatid Disease.—*Trans*
Roy Soc Trop Med & Hyg 1939 Apr 6 Vol. 32. No 6
 pp 697-706. [11 refs.]

The Ghedini Wernberg's complement fixation reaction and the
 Cason's intradermal reaction are group immunological reactions to somatic
 cestode infections rather than specific reactions for hydatid disease alone.
 Both hydatid cyst fluid and cysticercus cyst fluid gave a strongly positive
 complement fixation reaction with blood of either echinococcosis patients
 or cysticercosis patients. Both hydatid cyst fluid and cysticercus cyst
 fluid gave a strongly positive cutaneous reaction on patients with either
 echinococcosis or cysticercosis or intestinal taeniasis. The cerebrospinal
 fluid as well as the blood of most of the patients with cerebral cysticercosis
 gave a strongly positive complement fixation reaction. The serum of
 rats infected with *Cysticercus fasciolaris* gave a weakly positive complement
 fixation reaction with hydatid cyst fluid. The serum of four out of nine
 kala-azar patients gave a positive complement fixation reaction with
 hydatid cyst fluid of a 1:8 dilution. This positive reaction may be
 related to the high globulin content of the blood of kala azar patients.
 Extracts of different tapeworms are not satisfactory antigens for the

detection of somatic cestode infections because of their anti-complementary nature. The complement fixation test with hydatid cyst fluid as antigen may be utilized to detect cysticercosis in man (and possibly also in pigs and cows). Only the diluted hydatid cyst fluid (1:4 dilution) may be used as antigen for the complement fixation test for echinococcosis or cysticercosis, as the undiluted fluid very frequently gives a false positive reaction with the sera of patients with syphilis or other conditions. When ever both the Ghedini-Weinberg's complement fixation reaction and the Casoni's intradermal reaction are positive a differential diagnosis of somatic cestode infection and possibly also kala-azar must be considered unless the clinical picture is clear-cut.

SERGENT (Emile) FOURESTIER (Max) & GALLIANO (E. Jimenez)

Le virage de la réaction de Casoni après une deuxième ou plusieurs intra-dermoréactions. [The Activation of the Casoni Reaction after one or more Previous Intradermal Injections.]—*Bull Acad Méd* 1939 Feb 7 103rd Year 3rd Ser Vol. 121 No. 5 pp 180-182.

This paper and its discussion were summed up by Sargent in the statement that if the intradermal reaction of Casoni, in answer to hydatid fluid with no antiseptic in it, is positive on the first test a hydatid is certainly present.

On the other hand there are given instances where dissatisfied with a negative reaction to the first test it has been repeated once or twice with a final positive result and yet autopsy or operation have shown that the tumour has been a cancer the patient having been sensitized by the earlier injection.

SAWITZ (Wilh) Echinococcus Infection in Louisiana.—*Jl Parasitology* 1938 Oct. Vol 24 No 5 pp 437-439

A man of 72, who came to New Orleans when 8 years old and had not since left it, died with a clinical picture of liver cirrhosis with ascites. Autopsy showed a small nodular fibrous liver with a cyst 4 cm in diameter lined by a laminated chitmoid membrane. His work had been to feed and care for at a railway depot, animals sent by express. His family had never kept a pet dog. Two cases are noted in which *Echinococcus granulosus* was found by others in dogs in Louisiana, but the presence of cysts in sheep cattle and hogs is commonly reported.

ii. RÍSQUEZ (Rafael) Quiste hidatídico en Venezuela. [Hydatid Cyst in Venezuela.]—*Ibid.* pp. 195-197 [12 refs.]

1. This girl of 21 came under observation in a tuberculosis dispensary. Her general condition was good and her only trouble was headache. The sputum was free from tubercle bacilli but there was an X ray shadow at the base of the right lung. The Kahn reaction was slightly positive. It became negative after three months of intensive anti-syphilitic treatment but the character of the shadow was unchanged though in 5 months time it was bigger. An eosinophilia of 6 per cent. in the absence of facilities for complement fixation or intradermal reaction justified puncture and this produced a fluid free.

from albumin rich in chlorides and with many hydatid scolices. In discussion Risquez held that this is the first case in Venezuela confirmed by laboratory methods.

u. The author goes into the history of earlier locally reported cases but concludes that they are not convincing

HIYEDA (Kentaro) & TERADA (Banjuro) A New Anthelmintic "Raigan" for Taeniasis. [Research Notes.]—*Jl Parasitology* 1939 Apr Vol. 25 No 2. pp 183-184

Raigan is a sort of mushroom (*Omphalia lapidescens*) which grows on sandy soil where bamboo trees are luxuriant. It is dried to the hardness of stone and sold in the market.

It was used successfully in man for *Taenia solium*, *T. saginata* and *Hymenolepis nana* and apparently for *H. diminuta* and in the dog apparently for *Dipylidium caninum*. In no case was the scolex found but the worms had not reappeared in four months. The drug is believed to destroy the tissues of the worm, for the young segments evidently of the larger worms come away in small yellowish-brown motionless pieces and the bigger ones sometimes in chains. The segments of *Hymenolepis* were rarely seen. The treatment at first was with 20 grams of powdered Raigan three times a day for 3 days, and a complete cure it is claimed, was always obtained with no ill effects in over 100 cases, there being no preparatory treatment and no after purge.

After we had succeeded in extracting the active principle from the crude material, we reduced the doses from 20 gr. to 0.4 gr. The chemical nature of the active principle has not yet been determined. We shall be glad to supply this drug to investigators in large amounts at cost or in small amounts gratis.

BRETON (M.) & LAVIER (G.) Un cas de cysticercose musculaire généralisée décelée par la radiographie. (A Case of Generalized Cysticercosis of Muscles revealed by X Rays.—*Bull. et Mém. Soc. Méd. Hôp. de Paris*, 1938, Dec. 19 64th Year 3rd Ser. No. 34 pp. 1721-1725 With 1 fig.)

X-rays undertaken on suspicion of a latent prostatic neoplasm with vertebral metastases disclosed a most massive infection of muscle by cysticerci.

The man of 66 was very weak with general muscular atrophy, a fairly thick adipose tissue covering and no nodules palpable anywhere. Red cells 3,643,000 leucocytes 4,600 eosinophils 1 per cent. The X-ray shadows were most frequent in the muscles about the pelvis, the back and the pectoral region. The right leg was chosen for illustration because the shadows were discrete and their shape evident. The face probably showed two shadows. Excision of a nodule from the calf disclosed what was believed to be a calcified cysticercus. The infection has far from disappeared from France. C. L.

EVANS (R. R.) *Cysticercosis in an Athlete.*—*Trans Roy Soc Trop Med & Hyg* 1939 Jan. 28. Vol. 32. No 4 pp 549-550 With 2 plates

As an athlete this bandsman of 24 had played regularly for the band team in Association football and hockey had recently been tried out for the Battalion Rugby team and had represented the battalion in 120 yards hurdles relay race and cross country running. He had had nodules removed and identified as cysticerci but following this and a lumbar puncture he had an epileptic fit. In August 1937 he was admitted to hospital following a fit but pleading to be allowed to leave it he got second place for the long jump in the Highland Games at Crieff with a jump of 21ft. 5 in. He had never had a tapeworm or such symptoms of invasion as muscular pains rheumatism headache or fever. X ray plates show in the upper two-thirds or so of one thigh and in the thorax arm and neck, several hundred cysts and yet his athletic prowess seemed to be unimpaired. C L

AUSTONI (Miano) Su di un caso di cisticercosi generalizzata grave [Severe Generalized Cysticercosis].—*Policlinico Sez Prat.* 1939 Apr 3 Vol. 46 No 14 pp 627-30 633-6 639-43 With 11 figs. [30 refs]

A girl of 10 died of cysticercosis it being estimated that there were 15,000 to 20,000 cysts mostly in the muscles few in the abdominal organs and subpleurally in the lungs. During life submaxillary and dorsal swelling, exophthalmos headache vomiting fits and weakness were marked. The infection is attributed to *Taenia solium*. The considerable list of literature while going back to 1860 has no mention of English literature and of the great advances reported by MACARTHUR and others. C L

ALBERT (Zygmunt) Ein grosser Zystizerkus der *Taenia solium* in der Leber [A Large Cysticercus of *Taenia solium* in the Liver].—*Zent f Bakt I Abt. Orig.* 1938. Oct. 17 Vol 142. No 7/8 pp 374-376 [10 refs]

In the liver of a 36-year-old woman was a large cysticercus with abscess and subsequent peritonitis. It was identified as such by appearance and by the presence of an adult in the bowel. No trace of echinococcus was found in spite of careful search. C L

SEGAL (A) A Case of Cysticercosis of Bone.—*South African Med J* 1938. Oct. 22. Vol. 12. No. 20 pp 762-763

A condition believed to be chronic osteomyelitis of the right iliac bone displayed itself after three years to be a cysticercus infection.

A swelling in the right buttock was after 10 months excised as a cyst but on operation the diagnosis was changed to a ganglion containing sterile pus and originating from a diseased right iliac bone a diagnosis confirmed by X rays which displayed sequestra. These were removed, and sinuses eventually closed only to reopen shortly. It was then found repeatedly that when a needle was inserted into the swelling which was present it would withdraw a little fluid only, but if now put in in another direction more would come through it.

Finally it was drained of a large quantity of fluid, an intact grape-like cyst and several collapsed ones. PIJPER reported a typical cysticercus wall which, however, had no scolices. C. L.

ROMAN (E.) Sur l'infection des rongeurs par l'*Hymenolepis nana* de l'homme. [Infection of Rodents with *H. nana* from Man.]—*Ann. Parasit. Humaine et Comparée* 1939 Jan. 1 Vol. 17 No. 1 pp. 12-16. With 1 fig. [14 refs.]

Of five white mice fed on onchospheres of *H. nana* passed by a French girl with diarrhoea 1 was found infected when killed 4 days later. All the larvae were in the last quarter of the small intestine. C. L.

KOURI (Pedro) & DOVAL (José Macho) Tres casos de parasitismo humano por especies de la familia Davameidae. [Davamea Species in Three Persons.]—*Rev. Med. Trop. y Parasit. Habana* 1938, July-Aug. Vol. 4 No. 4 pp. 207-217 With 7 plates. English summary.

A preliminary paper in which determination of the species is not made.

The parasites were found in three children from 18 months to 9 years old, the last being reported in detail. He had had a tapeworm for 6 years and had suffered from an asthmatic condition, bronchitis, headache and weakness with anaemia (red cells 3.7 millions) and haemic mitral murmur. There were no eggs in the faeces but segments were passed. Treatment consisted of one of 12 capsules given every five minutes which in all contained 4 cc. of ethereal extract of male fern and 1 cc. of carbon tetrachloride the worm being expelled after the seventh capsule. LEÓN (Luis A.) Contribución al estudio de la parasitología Sud-americana. El género *Raillietina* y su frecuencia en el Ecuador [On South American Parasites. *Raillietina* in Ecuador]—*Rev. Med. Trop. y Parasit. Habana* 1938, July-Aug. Vol. 4 No. 4 pp. 219-230 With 9 figs. on 5 plates.

León reports the detection in Ecuador of nine infections of man by *Raillietina gusmanii* León, 1935.

The list of references does not include that in which he named the tapeworm. It is described as 10 to 12 metres long and 3 mm. broad with retractile rostrum and 2 rows of hooks, suckers ovoid and averaging about 1 mm. across with a surrounding row of persisting hooks. There are about 5 000 segments at first wider than long, then square and about 3 mm. across the terminal segments have 200 to 250 egg

capsules genital pores unilateral onchospheres oval with very long hooks definitive host man intermediate host unknown found in Ecuador It has caused abdominal pain nausea, diarrhoea, weakness headache vertigo and mental dullness. C L

BEARUP (A. J.) & MORGAN (E. L.) The Occurrence of *Hymenolepis diminuta* (Rudolphi, 1819) and *Dipylidium caninum* (Linnaeus, 1758) as Parasites of Man in Australia.—*Med Jl Australia* 1939 Jan. 21 26th Year Vol. 1 No 3 pp 104-106 [27 refs.]

Having noted that, in the Australian hookworm campaign under SWEET from 1919 to 1924 which examined 202 582 persons *Hymenolepis nana* was found in 0.2 per cent and *Taenia solium* or *T. saginata* in 0.02 per cent. there are reported three human infections with *H. diminuta* and two with *Dipylidium caninum* all in children. The two latter are believed to be the first recorded from the continent.

LIDDO (Salvatore) *Hymenolepis diminuta* nella provincia di Bari [*H. diminuta* in Bari Province Italy]—*Pathologica* 1938 Oct 15 Vol. 30 No 664 pp 436-437 [11 refs.] English summary (5 lines)

There were found in the faeces of a person 20 years old, the onchospheres of *Hymenolepis diminuta* eggs of *T. trichiura* a lamblia a bodo *E. coli* and *Blastocystis hominis* References are given to the 12 Italian cases. C L

PETROV (M. I.) New Diphylobothrids of Man.—*Med Parasit & Parasitic Dis* Moscow 1938 Vol. 7 No 3 [In Russian pp 406-413 With 10 figs. English summary p 414]

The author describes two species of diphylobothrids found by the 113th All Union Helminthological Expedition of the Institute of Tropical Medicine during medical treatment of the inhabitants of the Ventral national district of the Northern region. One of the species *Diphylobothrium skrjabini* had been described by Plotnikov as living in dogs and was for the first time found by the author in man. The second species, *Diphylobothrium nensei* is a new species.

LANE (Clayton) Points in the Diagnosis and Prevention of *Ascaris* Infection.—*New Zealand Med Jl* 1939 Feb Vol. 38 No 203 pp 23-26

A restatement of points, deemed important but too little known is made concerning the diagnosis and prevention of *Ascaris* infection.

As to diagnosis this section is essentially a comment on a statement by DEMPSEY [this *Bulletin* 1939 Vol. 36 p 320]. All authorities are agreed that the Willis technique is more accurate [than D.C.F.] in demonstrating ova of *Ascaris* and *Trichuris*. Uncertain as to what constitutes an authority Lane writing as a worker points out that to be soundly based comparative tests of diagnostic technique must rely on counts of the eggs which each recovers from the same evened material and that there are four essentials for successful diagnosis of *Ascaris* and *Trichuris* infections by D.C.F. namely—the presence of fertile eggs the proper disintegration of faeces the

use of a vessel large enough to prevent over-concentration, and a floating fluid whose *ascertained* specific gravity is just over 1,200. Special stress is laid on the last essential. When these essentials were fulfilled the collection of *Ascaris* eggs averaged 4 to 6 times greater by D.C.F. than by the Willis technique—moreover the lowest and highest counting by D.C.F. varied as 1 to 1.5 those by the Willis technique as 1 to 18 or 1 to 28 according as to which form of it was used. If there was used for floatation a three-quarters-saturated salt solution, the strength optimum for showing up hookworm eggs, the loss of *Ascaris* and *Trichuris* eggs was great. Stating the actual deliveries as percentages of a total content otherwise ascertained the figures for *Ascaris* got by D.C.F. and by the two variations of the Willis technique, when all used a saturated common salt solution, were 42, 7 and 13 and when all used a three-quarters-saturated solution they were 4, 1 and 3—the corresponding figures for *Trichuris* eggs were 25, 6 and 10 for the saturated and 1.6, 5 and 6 for the three-quarters-saturated solution.

As to prevention, some of the evidence for air-borne infection is repeated [see this *Bulletin* 1934 Vol. 31 p. 605] and the further evidence of HEADLEE [this *Bulletin* 1937 Vol. 34 p. 449] is noted. There is added the report by BULL [this *Bulletin* 1937 Vol. 34 p. 431] on the excellence of widely used borehole latrines as breeders of cockroaches and so as possible disseminators of *Ascaris* eggs, not as an advocacy for the discarding of latrines but as a reminder that the teaching of behaviour theoretically good may produce a condition practically bad—an urgent need of something better as a latrine—no easy matter to devise but admitting of no complacency or relaxation of effort.

C. L.

YOSHIDA (Sadao) & TOYODA (Harumaga). Artificial Hatching of Ascarid Eggs.—*Livro Jubilar do Prof. L. Travassos*. Rio de Janeiro 1933. pp 569-577. With 6 figs.

The essence of the results of this paper are found in its Table 7 which gives the percentage of "dog ascaris" "human ascaris" and "pig ascaris" eggs which have hatched out in five days in 17 different media. Taking "human ascaris" the average of the percentages of successful hatchings in media which are not digestive juices is 41.0. For the digestive juices they were—artificial gastric juice 22, bile 28, pancreatic juice 31, artificial intestinal juice 1. In these media the most favourable temperature was between 36° and 40°C. At temperatures down to 24° few embryos hatched, but those that did were more active and more resistant to chemicals. [The writers give no references. A number will be found quoted as for this *Bulletin* in the review 1934 Vol. 31 p. 605 in which also there is reference to BROWN's report that the only condition which inevitably produced hatching of mature eggs was drying followed by moistening.]

FLAXENT (Silvio) Contributo allo studio delle perforazioni intestinali da ascaridi. [On Intestinal Perforation by Ascaris.]—*Riforma Med* 1938 Nov 5 Vol. 54. No 44 pp. 1701-1703. With 1 fig

A child of 5 was admitted with evidence of acute appendicitis. On its operative removal, the head half of an *Ascaris* was found filling the lumen of an inflamed appendix, the tail half being passed in the first stool. Near the organ's apex there was a solution of continuity affecting mucosa and muscular coat with a haematoma under the peritoneum. On histological examination only the serosa was entire. Convalescence was uninterrupted. Literature on the subject is discussed but the editor found no room for the list of references. [See this *Bulletin* 1936 Vol. 33 p 109 1937 Vol. 34 p 23] C L

CAJADO (Itiberé de Castro) Occlusão intestinal por ascaris [Intestinal Obstruction by Ascaris.]—*Brasil Medico* 1938 July 16 Vol. 52. No 29 pp 657-662. [16 refs] English summary

After a tussle with a schoolmate the inguinal hernia in the right scrotum of a boy of 13 disappeared and he had severe right iliac pains. Internal strangulation of the hernia was suspected. Laparotomy revealed in the left iliac fossa loops of the ileum adherent to one another and filled it is said with a great number of ascarids and abundant faecal matter. The appendix was long and inflamed. It was excised the adhesions were cut through the mass in the ileum propelled into the caecum and pituitary extract given. Apparently the ascarids passed only numbered 12 in answer to a vermifuge given after his discharge from hospital. C L.

LECERCLE. Pancréatite aiguë hémorragique et ascaride. [Acute Haemorrhagic Pancreatitis and Ascaris.]—*Bull Acad Med* 1939 Mar 7 103rd Year 3rd Ser Vol. 121 No 9 pp 342-344

Acute rapidly fatal haemorrhagic pancreatitis of which a probable aetiological factor was the presence in the bile ducts near the duct of Wirsung of an *Ascaris* 22 cm. long C L.

CHANCO (Pedro P) Jr An Unusual Exit of an Adult Ascaris from a Child.—*Jl Philippine Islands Med Assoc* 1938 Nov Vol. 18 No 11 pp 709-714 [21 refs]

A child of 3 whose umbilicus had discharged at intervals since the cord separated after birth was seen to have a reddish projection from it which hurriedly withdrew when a stick of silver nitrate was put on it.

Next day it showed again, when wiped with cotton it came out a little further and was seized with forceps and pulled out with ease but evidently with pain to the child followed by great relief. There were still eggs in the faeces but the anus healed. [See this *Bulletin* 1935 Vol. 32 p. 257] C. L.

GHOSH (A. K.) A Case of *Ascaris lumbricoides* Infection simulating Cerebral Type of Malaria.—*Indian Med Gaz.* 1938. Oct. Vol. 73. No. 10 p. 614

VANNI (V.) Ascariodose et phénomène de Sanarelli. [Ascariasis and the Sanarelli Phenomenon.—*C. R. Soc. Biol.* 1938 Vol. 129 No. 34 pp. 1052-1055]

From the use of the coelomic fluid of *Parascaris equorum* for injection into rabbits it is concluded that ascarids contain a substance which produced in 3 of 20 sensitized rabbits the cutaneo-visceral haemorrhagic allergy described by Sanarelli.

There was massive shedding of epithelium particularly in kidney and intestine and haemorrhages into skin and viscera and, in line with experimental results, certain symptoms which occur in this infection in man and particularly in children (urticaria convulsions and asthma) are attributed to allergy in susceptible individuals caused by the body fluid of the worms C. L.

1. MACHEBOEUR (M.) & MANDOUZ (R.) A propos de la toxicité des extraits d'*Ascaris* [Toxicity of *Ascaris* Extracts.—*C. R. Soc. Biol.* 1939 Vol. 130 No. 10 pp. 1032-1034]

2. MANDOUZ (R.) Etude comparative de la toxicité des extraits d'*Ascaris* et de *Taenia* [Toxicities of *Ascaris* and *Taenia* compared.—*Ibid.* pp. 1035-1036]

1. The toxic substance which *Ascaris megalocephala* contains given intravenously in appropriate dose kills a guinea-pig in a few minutes. It is not precipitated by trichloroacetic acid and does not pass through collodion. It is not then a toxic amine like histamine nor an albumin or globulin, nor a toxin like those of bacteria, nor is it like a phytotoxin.

2. *Monilia expansa* has no such toxic substance as has *A. megalocephala*. That of the latter resides not only in the coelomic fluid but in the tissues and is far better extracted by trichloroacetic acid than by normal saline C. L.

RABIES

A REVIEW OF RECENT ARTICLES. LXXI

1. VIRUS.

KLIGLER and BERNKOPF¹ state that they have now succeeded in cultivating the virus of rabies in the developing chick embryo. In one

For the thirtieth of this series see this *Bulletin* 1939 Vol. 36 p. 193

KLIGLER (J. J.) & BERNKOPF (H.) Cultivation of Rabies Virus in the Developing Chick Embryo. [Correspondence]—*Nature* 1939 May 27 Vol. 143 No. 3630 pp. 899-900.

series the virus has been carried through nine and in a second through six successive passages without loss of virulence. The virus is present both in the allantois and in the brain but always in higher concentration in the latter. This success (*cf* this *Bulletin* 1939 Vol. 36 p 193) depends apparently on the age of the embryo at the time of infection as well as at the time of passage. With embryos of eight days or more the results are usually negative but embryos of 5-6 days are readily infected and serial passages can be maintained without any difficulty if they are made 9-10 days after infection. The embryo brain removed 9-10 days after the infection was infective for mice in dilutions of 1/1000 to 1/10000. Passages from embryo to embryo can be made with emulsions of either allantois or embryo brain.

The successful cultivation of the virus of Ajjeszky's disease on the chorio-allantoic membrane of the chick is reported by GLOVER.² The strain has now been carried through 55 generations. The strain has become modified in its effect upon laboratory animals. The period of incubation has been lengthened local pruritus is no longer produced and the characteristic pulmonary lesions are much diminished in intensity nevertheless the virus is still as lethal as infective rabbit brain. The observation of MESROBEAU (this *Bulletin* 1938 Vol. 35 p 643) is thus confirmed.

A test which it is stated distinguishes fixed from street virus is suggested by LEGEZYNSKI.³ White mice are inoculated intracerebrally with a small quantity of a 1 in 10 dilution. If the strain is fixed virus then the incubation remains constant in successive subpassages. On the contrary with street virus subpassages through white mice (after an initial passage in the rabbit) give varying incubations and after 4 to 6 the strain becomes avirulent and the mouse survives. A result of this nature cannot be obtained with white rats.

A process is described by NICOLAU⁴ for staining the elementary corpuscles obtained by fractional and repeated ultra-centrifugalization (3000 to 6000 revolutions per minute) and subsequent digestion by trypsin or papaine from suspensions of brain material of animals which died of rabies or of Ajjeszky's disease. A film is made of the deposit and dried at 37°C. This is fixed in the flame or in methyl alcohol. A staining solution containing —

Isamine blue (Grübler)	1 gm.
Carbolic acid	3 gm.
Ethyl alcohol	10 cc
Distilled water	100 cc

is poured upon the film which is warmed over a flame for 10 minutes. After washing in tap water and drying the film is examined. In both rabies and Ajjeszky's disease small coccal forms are seen with 1000 magnification. The dimensions of these forms vary from 90 to 250 μ .

A strain of virus designated J which had, during 187 passages covering 6 years, become fixed with an incubation period of 3 days, and with which Negri bodies had never been found in the horn of Ammon was kept by JOHANNESCO² in 30 per cent. glycerine at 6°C. for a period of 144 days. The first rabbit inoculated thereafter had an incubation period of 16 days, and numerous Negri bodies were found. After 15 subsequent passages the incubation had shortened to 3 days. Negri bodies were not found after 5 passages. Thus prolonged exposure to glycerine produces an alteration, which takes a number of passages to wear off.

h. Symptoms and Diagnosis.

After a comprehensive summary of the earlier literature relating to the paralytic form of human rabies, PAWAN³ cites a case which he observed in 1919 in Trinidad. The bite was inflicted by a cat, and the symptoms which supervened were inability to swallow and paralysis of the leg and body culminating in death. He then goes on to describe the symptoms which were observed in the epidemic of paralytic rabies in Trinidad in 1931.

A general article on the diagnosis of rabies in man and in animals is contributed by CORWELL.⁴

iii. Pathology

That infection with rabies can be achieved by the introduction of an emulsion of an aggressive strain of street virus into the bladder is shown by REMLINGER and BAILLY.⁵ Three dogs were so treated, and in each case rabies supervened, as shown by subsequent animal inoculation. The authors point out that this does not prove that infection took place through the mucosa of the bladder. The emulsion may on the one hand have ascended into the ureter and on the other the urethra may have been damaged, although every precaution was taken to avoid this latter possibility. The authors have obtained a positive result only with aggressive street virus strains.

In a second communication REMLINGER and BAILLY⁶ show that the virus of Aujeszky's disease is similarly transmissible. Out of three experiments with this virus two gave positive results.

Changes in the cholesterol and lipid content of blood serum and organs after infection with Aujeszky's virus are described by JOHANNESCO and ZICRAVESCO.⁷ Cholesterol which in normal rabbit serum

² JOHANNESCO (D.) & ZICRAVESCO (I.) La cholestérine dans le serum sanguin et les lipides totaux dans les organes, au cours d la maladie d'Aujeszky.—*C. R. Soc. Biol.* 1939 Vol. 130 No. 6 pp. 551-553.

measures 49.26 mgm per 100 cc. rises in Aujeszky's disease to 73.94. The lipoids of the brain normally 47.81 gm per 100 gm dry material decrease to 44.68. The lipoids of the heart increase from 20.97 gm per 100 in the normal rabbit to 24.35 in animals which have died of the disease. The lipoids in the spleen rise to 21.75 gm. per 100 as compared with 15.39 in the normal. Thus in Aujeszky's disease there is an increase in the cholesterol of the blood, an increase of total lipoids in the heart and spleen, and a decrease in the lipoids of the brain.

JOHNESCO¹¹ reports that he has obtained a powerful antirabic serum in an ass treated with phenol vaccine (5 per cent brain material 1 per cent phenol heated 3 days at 37°C). The neutralizing power of this serum has remained constant (1 to 5) during a year. Of 5 guineapigs which had been intracerebrally inoculated with rabies virus after having received three 10 cc. doses of antirabic serum three showed prolongation of the incubation period. The fresh serum of the immunized ass contained neurotoxins which gave rise to symptoms of irritation. Heating of the serum for 10 minutes at 56°C. or keeping it at 6°C. for 2 weeks destroyed the neurotoxins without affecting its viricidal power.

11. *Methods of Treatment and Statistics*

In a scholarly article REMLINGER¹² discusses the considerations which govern antirabic treatment. He discusses methods of treatment and in particular the relative efficacies of living and dead vaccines in the treatment of bitten persons. After summarizing the experimental and statistical evidence he concludes that phenolized vaccines have an efficacy at least equal to other vaccines and in particular to dried cords that they are inoffensive in that four times as many accidents occur with living vaccines as with dead that they can be produced with a maximum of economy and convenience. He draws attention to the fact that throughout the world more persons are treated by phenol vaccines than by all other methods combined, and that in no instance has an institute which adopted treatment by phenol vaccine abandoned this method of treatment and reverted to its original method.

In a further communication REMLINGER and BAILLY¹³ describe experiments comparing treatment by dried cords with treatment by phenol vaccines (Semple). Of 10 rabbits treated with dried cords 7 contracted rabies of 20 treated by Semple's vaccine 12 died whilst of an untreated control group of 12 9 contracted the disease. In a similar experiment with dogs 2 out of 8 died after treatment with cords 3 out of 10 after treatment with Semple's vaccine and 7 out of 8 of the untreated. They conclude from these experiments that Semple's vaccine affords a degree of protection at least equal to that given by dried cords.

A series of experiments has been carried out by LÉVINZ and SAUTTER¹⁴ to determine whether there is any difference in the time of appearance of immunity after treatment by dried cords and treatment by Fermi's phenol vaccine. To answer this question parallel groups of rabbits received daily treatment for 5, 10 and 15 days by each of the two methods. These treatments were so arranged that the last injection for each series was given on the same date. Ten days later a test dose was given to each animal. It appeared that with a treatment of 5 days by dried cords the incubation period was prolonged but no animal was saved, whilst treatment by Fermi's vaccine was totally efficacious. With a 10 days treatment by dried cords 5 out of 8 contracted rabies whilst when the treatment was that of Fermi there were no deaths from rabies amongst 4 animals. With 15 days treatment in the case of dried cord treatment 3 of 3 died of rabies, whilst in the case of Fermi's treatment none out of 4 contracted the disease. The authors conclude that 10 days is a minimum for treatment by Fermi's method, and that even 15 days is efficacious when treatment is by dried cords although a certain "precocity" in the date of onset has been observed. [Confirmation of these results would appear to be called for.]

Experimental observations on the results of treatment of mice with formalized tissue culture virus are reported by KLIGLER and BERNKOPF.¹⁵ The cultures were prepared according to the method of Webster and Clow. After 4 to 5 days incubation the cultures were centrifugalized in large tubes the supernatant fluid removed, and the sediment triturated with a glass pestle. The ground material was resuspended in the supernatant fluid and 0.1 per cent formalin added. As a rule the titre of the culture was tested by mouse inoculation before adding the formalin: the cultures used contained from 5,000 to 50,000 lethal mouse units per cc. All vaccines were tested for sterility and also for inactivity by intracerebral inoculation into at least 2 mice."

A first series of experiments was designed to ascertain the immunizing effect of varying doses and number of injections. Out of a total of 29 mice given 5 to 7 injections of inactivated virus intraperitoneally 13 (45 per cent.) were fully immune to at least 10 lethal intracerebral mouse units of test virus, and 4 (13.5 per cent.) were partially immune as indicated by prolonged incubation period (14 to 24 days) 2 or 3 times that of the controls. One group of 8 mice which received only 1 injection of vaccine succumbed to the test virus in the same period as the controls. The controls numbered 13 none of which survived the test dose.

In a second series the test dose was given intraperitoneally. In this case immunity was more easily established, and it was found that "even a single intraperitoneal treatment with the inactivated culture virus is sufficient to protect mice against an intraperitoneal infection with a dose of fresh virus which kills about two-thirds of the control mice. A similar immunity is conferred against a subcutaneous infection except that a larger amount of vaccine is required."

From 1919 to 1928 the vaccine employed in Prague was prepared after the formula of Cumming. Owing to the occurrence of paralytic sequelae the method was at the latter date changed to that of Fermi and since then no troublesome sequelae have been encountered. From various experiments BOUČEK¹⁶ found that phenol in a concentration of 1 per cent had a toxic action on mice. He has accordingly introduced a modification. A 10 per cent suspension of brain substance in 1 per cent phenol saline is prepared and kept at 20°C. Before use the suspension is diluted with an equal quantity of normal saline. Such a suspension induces no toxic symptoms in mice, and the immunizing properties of the vaccine are not impaired.

An epizootic of rabies commencing in November 1934 is described by LEWILLOX¹⁷. Following the canine epizootic twelve persons were given antirabic treatment. One of these in spite of treatment by Fermi's method died of rabies.

Of 2 331 persons treated at the Haffkine Institute at Bombay¹⁸ during the year 1936 2 (0·08 per cent) contracted the disease in spite of treatment by Semple's vaccine. Full statistical tables relating to the persons treated are given by SOKHEY.

Of 2,399 persons treated in Palestine¹⁹ during the year 1937 2 (0·10 per cent) contracted the disease. The vaccine used is that of Semple. One neuro-paralytic accident occurred. The case proceeded to recovery. It is of interest to observe that this is the first case of paralytic accident in Palestine since 1932 since which year 8 741 persons have received antirabic inoculations.

Rules regarding the indications for antirabic treatment as applied in the German Institutes are published by BOECKER and JAHN²⁰.

v Rabies in Animals

An epizootic of rabies commenced in the Settlement of Singapore²¹ in June 1937. During the months of September October and November eleven dogs died of the disease making a total including the original case of twelve cases five of which occurred in dogs which had been vaccinated prophylactically. Mass vaccination was carried out from September onwards and a total of 11,942 dogs were treated.

SMITH, MCGUIRE, STEPHENS and LAHIRI²² draw attention to the fact that no death from hydrophobia has been reported at the Pasteur Institute at Kasauli and its out-centres during the past 30

vi. Post Vaccinal Paralysis.

A case of accident after treatment by Calmette's method is described by HORACK.³³ The patient developed encephalitis but showed no symptoms of paralysis. The patient's family history and the manner in which he reacted to the vaccine suggested that the local reactions and early manifestations of generalized lymph node enlargement might be viewed as an allergic response to the protein contained in the nervous tissue of the vaccine and that the clinical picture of encephalitis which followed (papilloedema headache vomiting, increased c.s.f. pressure) might likewise be an allergic response to the protein of the inocula. Impressed by this Horack made a survey of 16 persons known to have had severe accidents as the result of treatment and compared them with a control group of 45 persons in which no neuroparalytic accidents had occurred. In 87.5 per cent. of the former group personal or family history of allergic disease was elicited, as compared with 33.3 per cent. of the latter. A method of desensitization was successfully employed in 3 cases which had, or developed, a marked sensitivity to the antirabic vaccine.

vii. Miscellaneous.

In a lengthy article BALOZZI³⁴ discusses rabies as it occurs in tropical and subtropical countries, its geographical distribution the animal vectors and the nature of the strains of virus. *Oulon feto* and the epizootics of paralytic rabies which occur in South America are dealt with, and measures of prophylaxis and treatment are discussed.

A summary of present-day knowledge regarding the bat borne rabies is given by EVERLING²⁵. He deals first historically, with the epizootics among cattle and horses in South America then with the human epidemic in Trinidad and finally with the rôle of the bat in their transmission.

A short description with illustrations of a living *Desmodus rotundus rotundus* sent to Paris from the Argentine is given by ROMAÑA.²⁶ This is followed by a short note on the various species of *Desmodus* which are concerned in the transmission of rabies.

An interesting article on rabies in Trinidad and in particular on the rôle of the vampire bat in its transmission is contributed by SLIMON.²⁷

KIRK²⁸ reports that sulphanilamides appear to have no effect on rabies. Three rabbits were infected subdurally with fixed virus (Paris strain) and given 1 cc. daily of Prontosil soluble intra venously for the following six days. A fourth was kept as a control. All four rabbits were moribund by the seventh day and showed typical symptoms of paralytic rabies.

From a study of the records of 7 200 rabbits which had been infected with rabies at Tonking during a period of 5 years DODERO²⁹ finds evidence of seasonal variation. The year at Tonking is divided into 3 seasons the first from February to April when the climate is fresh and moist the second from May to October when it is hot and rainy the third from November to January when it is fresh and dry. The mean duration of incubation diminishes abruptly from April to June and rises again slowly during November and December. The curve of the mortalité precoce (that is the proportion of rabbits which die before the date at which they would ordinarily be killed for vaccine) is lowest in February and highest in October (Figs 2 and 3 of this article should be transposed.)

That the blood of animals suffering from rabies is rarely infective is well known. REMLINGER and BAILLY³⁰ in a recent experiment failed to obtain infection from the blood of 12 infected rabbits the blood being drawn at different stages of the infection and inoculated in large quantity into the muscles of the neck of guineapigs (2 in each case). The extreme rarity of positive results adds interest to two observations in which blood was taken not directly from the infected animals but from ticks which infested them, and in which infection with rabies resulted from inoculation of this minimal quantity of blood. These two positive results occurred in a series of similar experiments on 30 dogs. The ticks which were used were of the

species *Rhipicephalus sanguineus*. Similar experiments with leeches (*Limnatus nilotica*) gave negative results. The authors do not suggest that the tick may convey infection to man. It is however possible that the virus of rabies may develop in the stomach of the tick.

In a second paper²¹ the same authors discuss the paresis which may develop in man from the bite of a tick and describe experiments on rabbits and guinea-pigs in which a non-fatal paresis but not a paralysis developed after inoculation of the stomach contents of ticks which had been fed on healthy dogs.

The relationship between concentration of galactose in the urine and local reactions during anti-rabies inoculation is discussed by CRUVEILHIER, DIERYCK and VIALA.²² In the urine of 14 out of 15 persons who experienced erythema or urticaria, the concentration of galactose was increased as compared with a normal as derived from 9 persons who were unaffected by local reactions. The authors attribute this variation to a functional deficiency of the liver which gives rise to hypersensitiveness. A. G. McKendrick

TRYPANOSOMIASIS

PRÉCIS OF ABSTRACTS IN THIS SECTION

The Report of the Sleeping Sickness Service of Nigeria for 1937 (p. 736) is mainly a record of administrative matters, but from an experiment on two patients it is concluded that four 2 gm doses of trypanamide did not increase the resistance of the parasites to this drug.

From a study of the 68 inhabitants of a village in Southern Rhodesia, BLAIR (p. 736) concludes that there is little evidence to support the view that *T. brucei* and *T. rhodesiensis* are identical, and that infection is not stored in a game animal reservoir. In this village there were 2 persons with *T. rhodesiensis* in the blood and tsetse flies were abundant yet other inhabitants were not infected, though European and native visitors had been infected. These visitors had either not before been exposed to tsetse or had been exposed only to low densities.

CORSON (p. 737) records chronic infection in monkeys infected with *T. gambiense* through *G. morsitans* and suggests that similar chronic infections possibly undiagnosed, may occur in man.

LEFROU and GOARNISSE (p. 738) demonstrate that in the Ivory Coast non-infected persons show very much the same ocular lesions as those infected with sleeping sickness. Optic neuritis may occur in the uninfected and in the infected before treatment but papillitis may be due to a second stage disease. It does not suddenly end in atrophy. Old cases of trypanosomiasis in adults often show complete decolouration of the papilla, and in these medication with pentavalent arsenicals undoubtedly plays a part in the production of optic atrophy.

The authors discuss other conditions in connection with the aetiology of ocular lesions

SYMES and SOUTHBY (p 740) report on the reduction of *G. palpalis* by the block method over an area of 713 acres along the shore of Lake Victoria. Hand-catching of adults was more effective than collection of pupae and trapping was ineffective. The decrease in the numbers of *G. palpalis* was from 50 to 90 per cent and the total cost about £878. Large numbers of flies cross stretches of open water 400 yards wide. Elimination was not achieved but even with high densities of fly hand-catching can be employed successfully and economically and it is hoped that eradication will soon be completed.

As a result of further observation of volunteers for experimental infection with *T. rhodesiense* CONSON (p 741) finds that they remained so well in health after completion of treatment that he now thinks that some of the complications suffered by them while treatment was in progress may have been due to the germanin used. HAWKING (p 742) found that germanin had practically no trypanocidal action on *T. rhodesiense in vitro* but that trypanosomes incubated with it and then inoculated into mice failed to infect. The amount absorbed by these trypanosomes was small. In the estimation of germanin in the blood VIERTHALER and BOSELLI (p 742) point out that the serum of small animals before administration of the drug gives some yellow colouration which varies from day to day with the reagents used. It is therefore necessary to estimate this colouration shortly before administration. The amount of germanin in the blood falls slowly and protection against subsequent infection with *T. brucei* is afforded at levels as low as 1 mgm. per 100 cc. VAN DEN BRANDEN (p 743) obtained prolonged incubation period and temporary sterilization of the blood by exposing rats to the vapour of germanin before and after *T. brucei* had appeared in the blood.

POP and BUDAC (p 743) found that anticomane has only a feeble therapeutic action in rats infected with *T. brucei* and *T. equiperdum* but that the prophylactic action was rather better though the drug must be given at the same time as the infection. Its action is directly on the parasites.

LAGODSKI (p 743) failed to protect a rabbit by a dose of p-aminophenylstibimate of methylglucamine against subsequent infection by an arsenic resistant strain of *T. annamense* but there was a definite influence in attenuating the virulence and pathogenic power of the parasite.

VAN DEN BRANDEN (p 744) concludes that astreptine has no action on rats infected with *T. brucei*. The sulphate of ortho-oxo-quinoline has some trypanocidal action *in vitro*.

LAUNOY (p 744) found in mice that a single dose of 4 cgm. orsanine was more lethal than the same amount given in 3 separate doses at 4 and 3 hours interval. A large single dose effected more cures in mice infected with *T. brucei* than the same amount spread over several doses, and the longer the intervals the less was the efficacy of the drug. He considers that similar tests should be made in man.

MANNOZZI TORINI (p 745) gives a method depending on the differential centrifuging of blood containing trypanosomes and diluted with citrate-saline for obtaining an emulsion of living trypanosomes for experimental work. He (p 745) showed that proteolysis occurred in a mixture of *T. evansi* and casein on incubation at pH 5.9.

ROUBAUD and PROVOST (p. 746) observed that the growth of three young mice infected with *T. gambiense* was arrested especially one which lived for 5 months after infection. Infantilism has been recorded in infections with *T. evansi*.

NICOLLE and SIKORS (p. 746) observed that the sedimentation rate in guinea-pigs infected with *T. equiperdum*, *T. brucei* and *T. evansi* was increased. YORKE in comment thinks that this phenomenon is to be related to the auto-agglutination which he has shown to take place in trypanosomes if the blood is cooled.

FRENCH (p. 747) working with *T. congolense* and *T. brucei* in animals finds a sharp fall in blood sugar before a crisis or death. Acidosis exists and increases before death and blood lactic acid increases.

BIRKS (p. 747) shows that there is considerable difference in the susceptibility of individual small laboratory animals to *T. congolense* and that different strains of the trypanosome appear to vary in pathogenicity. Conclusions drawn from a small number of inoculations therefore are likely to be fallacious.

DELIDIMITRIOU (p. 747) obtained hopeful results in the treatment of 270 cattle with surfen C. The infection was with *T. congolense*. VAN SACZGHEM (p. 748) also reports favourably on surfen C given intramuscularly in doses of 1 gm per 100 kilo in cattle. This may be repeated after 5 days. The drug acts better in *T. congolense* than in *T. evansi* infection.

T. equiperdum multiplies readily in rabbit's testicles and lesions develop in 4-8 days. SOLDANI (p. 748) makes use of this fact for the diagnosis of dourine when trypanosomes may be difficult to find. He inoculates the blood or better serous fluid from the genital lesions into the testicles of a rabbit. For purposes of diagnosis he prefers this method to the intrapalpebral reaction of Lanfranchi and Soudi, the formolgel or the complement fixation test.

ZWEIMER and CLIBERTSON (p. 748) noting the similarity between the terminal spazms in rats infected with pathogenic trypanosomes and those observed in cases of potassium poisoning examined the serum potassium level throughout the course of infection of these animals with *T. equiperdum* and found that there is a marked increase beginning 24 hours or so before death. They infer that this is the direct cause of death rather than an endotoxin, a hypoglycaemia or asphyxia.

POINDENTER (p. 748) notes that young rats respond to *T. equiperdum* infection by increase of mononuclear leucocytes more readily than do older animals. This trypanosome was rendered avirulent if not actually killed, in 20-30 minutes when subjected to a temperature of 41°C.

HOLMER and RULE (p. 749) found that sulphamamide orally or intravenously was ineffective in the treatment of rats infected with *T. equiperdum*.

JALFREY (p. 749) found that antiplague vaccination of cattle in Cambodia produced rise of temperature which in 5 per cent. of some thousands of cattle over 8 years old, was accompanied by the presence of *T. evansi*. This, however, reacted readily to naganol. It is inferred that these cattle are a reservoir of *T. evansi*.

LLOVEROL (p. 749) reports good results from treating sheep inoculated with *T. dimorphum* with 15-20 cc. of normal *Cynocephalus* serum. In debilitated animals there is grave risk in applying such treatment.

DUCA (p 750) investigated the cause of susceptibility of young rats to *T lewisi* as compared with older rats. This infection was found to be highly pathogenic for rats less than 25 days old and survivors showed a marked leucocytosis and monocytosis. In fatal cases there was marked secondary anaemia but absence of this leucocyte response. CULBERTSON and KESSLER (p 750) rendered rats—the older more easily than the young—resistant to *T lewisi* by repeated injection of formalized homologous antigen. CULBERTSON (p 751) observed that when germanin was injected into nursing rats infected with *T equiperdum* the parasites were observable for 30–36 hours whereas in older rats they disappeared within 15 hours owing it is believed to the reticulo-endothelial response by way of which the drug is thought to act.

He (p 751) finds that resistance to *T lewisi* infection is conferred upon young rats nursed by a mother who has been passively immunized after parturition. The same author (p 751) found that specific antiserum given *per os* (0.5 cc per 10 gm body weight) imparts to young rats resistance to infection by *T lewisi*. This resistance diminishes with age and in old rats is nil. It may be that the intestine becomes impermeable to the antibody or denaturizes it. He again (p 752) in order to ascertain whether increased resistance with age of the subject (man and animals) was due to enhanced reaction on the part of protective cells inoculated rats ranging in age from 6 to 60 days with 1 per cent trypan blue killed them 18 hours later and examined the phagocytic activities of the tissue cells. The only variations worth noting were in the liver—the Kupffer cells in the older rats revealed a much greater phagocytic activity than those in the younger. The author takes this as answering his query in the positive.

MAZZA and his colleagues (p 752) in a series of papers record cases of Chagas disease in various parts of the Chaco country and have noted that a fairly large proportion of *Triatoma infestans* caught in the dwelling were infected.

BRUMPT (p 753) brings further experimental evidence to support the view that it is by way of the excreta and not by bite that reduviid bugs transmit *T cruzi* infection.

PIFANO (p 753) on the ground that *Psammolestes arthurii* a reduviid bug of Venezuela is easily infected experimentally with *T cruzi* thinks it may possibly be a natural transmitter. This insect has not yet been found outside Venezuela. FERREIRA and DEANE (p 754) made analogous observations regarding the Hemiptera *Clerada apicicornis* which is widely distributed in the Amazon estuary where many animals are found naturally infected with *T cruzi*.

DEANE and JANSEN (p 754) have found a small opossum *Marmosa cinerea* a reservoir host of *T cruzi* in the State of Pará.

TALICE and RIAL (p 754) report yet another case—this is called the twentieth—of Chagas disease in Uruguay.

KOLODNY (p 755) has carried out, with *T cruzi* investigations analogous with those of CULBERTSON on *T lewisi* (v.s.) regarding the increasing resistance of rats with age. Susceptibility is marked to the time of weaning (25–35 days) after which resistance is observed and increases to a maximum at maturity though still existent through life. This is not due to any specific antibody because injection of the serum of normal adult rats did not affect the course of infection in young susceptible animals. The resistance is present whether infection is *per os* or by the peritoneum. The same author (p 755) has observed

that with *T. cruzi* (as has been noticed with diphtheria toxin in guinea pigs, and the viruses of encephalitis and endemic typhus in mice) young rats suffer less in the summer than in the autumn winter and early spring.

ROMANA (p. 756) has produced his sign experimentally by conjunctival deposition of the faeces of an infected *Rhodnius prolixus*.

H H S

NIGERIA. REPORT ON THE MEDICAL SERVICES FOR THE YEAR 1937
[BRIERCLIFFE (R.) Director] Appendix B pp. 67-73—Report
of the Sleeping Sickness Service, 1937

The year 1937 has been a period of transition. The Colonial Development Fund is providing £19 000 per annum for five years for sleeping sickness control measures on the understanding that Nigeria provides a further £11 000 for the expansion and improvement of treatment in addition to maintaining the normal running of the service. The appointment of a second entomologist and ten sleeping sickness control officers was approved, and the entomologist five of the control officers and a foreman arrived in October. Six of the eight R.A.M.C. British Non-Commissioned Officers who were to take over the sleeping sickness teams arrived towards the end of the year. While the new officers were being trained, work was continued on the same lines as in 1936.

Owing to shortage of staff, it was rarely possible to keep more than one officer at Gadam. A full programme of entomological work has been continued there and some chemotherapeutic research has been done. The experiment on trypanamide resistance referred to in the 1936 report has been continued. Thirty monkeys were injected with blood from untreated sleeping sickness cases and after the patients had received four 2 gm. injections of trypanamide another series of monkeys was inoculated from them. In two instances the strain was isolated both before and after treatment. The characteristics of the two strains have been studied but no significant differences could be detected, from which it is concluded that in these two patients four 2 gm. doses of trypanamide did not increase the resistance of the parasite to the drug.

Owing to the absence of the entomologist from Gadam, there has been no opportunity of working out the research data which had been accumulating. The report concludes with certain remarks on therapeutic measures, sleeping sickness control and the Anchan Settlement Scheme.

BLAIR (D. M.) Human Trypanosomiasis in Southern Rhodesia, 1911-1938.—*Trans. Roy. Soc. Trop. Med. & Hyg.* 1939, Apr. 6, Vol. 32, No. 6 pp. 729-742. With 1 map. [10 refs.]

The paper commences with a description of the history of tsetse fly occupation in Southern Rhodesia, the position today and the outlook for the future. The author then deals with the history of human trypanosomiasis in Southern Rhodesia and with the events leading up to the 1934 Medical Survey. Cases of human trypanosomiasis reported in Southern Rhodesia from 1909 to 1938 are shown in a table. In all there have been eight European cases with six deaths, and 45 native cases with 29 deaths.

Special reference is made to the state of affairs in the Gowe district. This is a thickly wooded river plain situated at the junction of the Umnati and Msongwa rivers. It has a large and varied game population and was always heavily infested with tsetse. When the author visited it in 1935 he found the tsetse not only in the surrounding bush but right in among the huts of the village where they proved extremely troublesome. This is not a usual finding in villages of similar size situated in fly areas and Blair believes that it has an important bearing on the epidemiology of sleeping sickness in Southern Rhodesia. The present inhabitants settled in Gowe in 1930 having moved from a site about 25 miles to the south and the community now consists of 5 alien native fishing boys and indigenous natives comprising 8 adult males, 25 females and 28 children. Their communal health had on the whole been good, and there was no record of outstanding mortality.

On the afternoon of his arrival the author examined the whole population but because of the annoyance caused by the tsetse fly material secured was not examined on the spot but taken to Robb's Drift. Two so-called carrier cases of trypanosomiasis were discovered, viz. Kahondera the headman of the village and Zarro a middle-aged male. Blood films in each case showed a heavy infection with *T. rhodesiense*, *P. falciparum* and *Microfilaria perstans*. Neither patient apparently gave any definite history of illness. Details are given of a number of cases which can be directly connected to the Gowe focus.

Summarizing his experience at Gowe the author concludes that it lends little support to the view that *T. brucei* and *T. rhodesiense* are the same organism. Blair believes that a local outbreak of the disease always follows the establishment of the man fly man cycle and that the infection is not stored in a game animal reservoir but in a human reservoir. In the case of Kahondera the trypanosomes were present in the peripheral circulation at every examination and in relatively large numbers so that he would act as an extremely efficient reservoir. The genesis of the carrier state is a very interesting problem. Kahondera's trypanosome had the virulence and lethal effect on experimental animals associated with *T. rhodesiense* infections. If it is presumed that Kahondera and Zarro infected the village tsetse the flies were apparently unable to produce any acute cases of the disease in the other inhabitants of the village and yet they were able to infect quite a large proportion of the casual visitors to the village both European and native these visitors being individuals who had either never been exposed to tsetse before or only exposed to low fly densities. The paper concludes with certain speculations on the explanation of carriers.

CORSON (J. F.) A Final Note on a Strain of *Trypanosoma gambiense* transmitted through Monkeys by *Glossina morsitans*—*Ann. Trop. Med. & Parasit.* 1939 Mar 31 Vol. 33 No. 1 pp. 91-93

This note concludes Corson's observations on the strain of *T. gambiense* transmitted through monkeys by *G. morsitans* [this *Bulletin* 1937 Vol. 34 p. 921 and 1939 Vol. 36 p. 208]. Attention is drawn to one or two errors in the table of the third note viz. monkey 115 had lived for 238 days instead of 537 as stated and monkey 110 had lived for 202 days and not for 501. About the end of 1938 Corson decided to end the experiment by chloroforming the remaining monkeys.

and examining the cerebrospinal fluid macroscopically. The results are shown in a table. Details are given of 13 monkeys, which lived for periods varying from 289 to 1 174 days after inoculation. Trypanosomes were found in the cerebrospinal fluid of five of these monkeys and the cell count was considerably increased in all except one. It is interesting to note that the findings in the monkey which lived 1 174 days were trypanosomes 50 and white cells 640. Corson states that the interest of such infections in susceptible monkeys is that they suggest that similar chronic infections, possibly undiagnosed, may occur in man. W I

LEFFOT (G) & GOARNISSON (J) Les lésions oculaires chez les noirs trypanosomés avant tout traitement. L'importance des carences alimentaires. [Ocular Lesions in Natives Infected with Trypanosomes before Treatment the Importance of Alimentary Defects.]—*Bull. Soc. Path. Exot.* 1939 Apr 4 Vol. 32, No 4 pp. 424-437

It appeared to the authors, who wished to study systematically the lesions occurring in the depth of the eye during treatment of sleeping sickness that it was essential to know first what changes were found before any treatment was administered.

The authors carried out their work at Onagadougou in the Mossi country of the Ivory Coast. They examined 1 232 cases of sleeping sickness—425 new and 807 old cases. The latter had in general received only one course of atoxyl or trypanamide in 1935. As a control the eyes of 537 persons not suffering from trypanosomiasis were also examined. The difficulties confronting ophthalmoscopic examination of natives are mentioned, and the manner in which these difficulties were overcome is discussed. The results of the investigation are summarized in a table in which the nature of the lesions, the period of the disease and the sex and age period (man, woman or child) are given. These tables are so interesting that they are reproduced here.

Results of Ocular Examinations of Trypanosomal and Non-Trypanosomal Natives

It will be seen that the non infected persons show very much the same lesions as those infected with trypanosomes. Women exhibit slight pallor of the papilla much less frequently than men and children and complete decolouration indicative of optic atrophy is more common in men than in women and children.

The evolution of the disease towards the second stage seems to exert a special influence on the appearance of papillitis contrary however to general opinion this early stage of optic neuritis does not suddenly end in atrophy the latter lesion is much less frequent than the former. Attention is drawn to the fact that papillitis is rare in old treated cases. Optic neuritis is often only a manifestation of a localized meningitis of the sheath of the optic nerve.

There is a trypanosomal papillary neuritis just as there is a syphilitic papillary neuritis. As this neuritis is not associated with diminution of visual acuity and can only be recognized by the ophthalmoscope it is often unnoticed.

Old cases of trypanosomiasis in adults exhibit more frequently complete decolouration and in these medication with the pentavalent arsenicals undoubtedly plays a part in the production of the optic atrophy, the optic nerves of adults being much more sensitive than those of children. Recent cases showed pallor in 20.4 per cent. of cases, complete decolouration in 2.6 per cent., papillitis in 6.1 per cent. and chorio-retinitis in 1.8 per cent. Old cases showed slight pallor in 13.6 per cent., complete decolouration in 3.5 per cent., papillitis in 1.4 per cent. and chorio-retinitis in 0.9 per cent. In all 31.7 per cent. of recent cases and 30.1 per cent. of old cases exhibited ocular lesions.

The general conclusion appears to be firstly that before any treatment sleeping sickness patients may present ocular lesions, particularly optic neuritis, and secondly that such lesions are not necessarily pathognomonic since they are found in non infected cases.

The remainder of the paper is concerned with a discussion regarding the aetiology of the ocular lesions. The authors consider the possible influence of syphilis and of filarial and other helminthic infestations. They then go on to the question of nutritional deficiencies, and state that they are very inclined to think that in Mosen the minor signs of optic neuritis such as a simple pallor of the papilla are due principally to defects of diet which appears to be particularly poor in vitamin C and to a less extent in vitamin A. The paper should be consulted in the original by those interested.

SYMES (C. B.) & SOUTHERN (R.) The Reduction of *G. palpalis* in a Lake Shore Area by the "Block" Method.—Fol. 4+32 pp. With 4 folding diagrams, 1 map & 22 photographs. 1938. Nairobi. [Summarized in *Rev. Applied Entom.* Ser. B. 1939. May. Vol. 27. Pt. 5. pp. 63-69.]

"A detailed account is given of an experiment carried out between March 1935 and September 1937 in which an attempt was made to eliminate *Glossina palpalis* R.-D. from an area along the shore of Lake Victoria in Kenya Colony by the "block" method which had been used successfully along infested rivers. Brief notes are given on the topography, vegetation, climate and fauna of the area and on the incidence of sleeping sickness and the habits of the population. Descriptions of the 8 clearings include their locations, dimensions, the type of original bush that had to be cleared, the cost and progress of clearing and their present state. The technique used for reducing the fly is outlined, and descriptions are given of each block together with the details of the measures carried out and the results obtained. Points of interest relating to trapping, to the bionomics of *G. palpalis* and of *G. pallidipes* Aust. and *G. brevipalpis* Newst. the two other species of tsetse fly found in the area, and to the recovery of the fly population after reduction by collection of adults and pupae are discussed.

"The following is taken from the authors' summary and conclusions. A total area of 713 acres was cleared at a cost of approximately £900. The amount of clearing was about twice as much as that necessary for isolating the infested blocks of bush, the extra clearing being undertaken to facilitate early settlement and agricultural production. Fly reduction was accomplished by hand-catching of adults, collection of pupae and trapping. The first method was the most economical, the second was much more costly, and the last was ineffective. The

decrease brought about in the numbers of *G. palpalis* on the mainland varied between approximately 50 and 90 per cent. the small fly population on Hanete Island was practically eliminated in 3½ months. The total cost of fly reduction measures excluding the nominal value of traps was approximately £878. Data collected indicate that *G. palpalis* can maintain itself at a low density by breeding in sugar-cane and banana plantations. Its pupal period in the area concerned lasts 43-53 days. The season of its maximum activity is from April to June and that of maximum reproduction from April to September. Considerable movement of fly occurs along the shore and between the mainland and islands and although this is aided by pedestrian and canoe traffic, large numbers of flies cross stretches of open water as much as 400 yards wide. The periods of maximum adult activity and maximum reproduction in *G. pallidipes* and *G. brevipalpis* occur at the same time as those of *G. palpalis*. Settlement and development have progressed satisfactorily. Elimination was not achieved, but the reduction accomplished and the experience gained indicate that even with high densities of fly hand-catching can be employed successfully and economically. It is hoped that the eradication of *G. palpalis* in this area will be completed in the near future.

CORSON (J. F.) A Further Note on Some African Volunteers in Experimental Work with *Trypanosoma rhodesiense*—*Ann Trop Med & Parasit* 1939 Mar 31 Vol. 33 No 1 pp 97-99

In a recent note [this *Bulletin* 1939 Vol. 36 p 667] the author recorded a somewhat high incidence of various illnesses in Africans who had volunteered for experimental infection with *T. rhodesiense*. These illnesses occurred during or after treatment with germanin both in patients who had become infected and in others who had resisted. The author concluded that there was no reason to attribute these complications except albuminuria, to the action of germanin or to infection with *T. rhodesiense* and suggested that such illnesses were not exceptional in the local population to which the volunteers belonged. Since writing the above about the middle of October 1938 the author was able to see nearly all the volunteers weekly up to February 1939 when the present note was written.

Of the original 43 1 had died and 4 had left the district. Of the remaining 38 only 3 had anything more than trivial disturbances of health. One of these had diarrhoea in October and a short attack of acute bronchitis with fever in November. The second had diarrhoea and an undiagnosed fever of four days duration in November and the third suffered from pain in his left foot which lasted nearly a month. The last case is of interest because a few other volunteers had complained of similar pains during or soon after treatment and one had obviously suffered from very severe pain. LESTER [this *Bulletin* 1937 Vol. 34 p 521] reported mild peripheral neuritis after the administration of germanin and thought the drug had caused it.

Excluding such infections as malaria, relapsing fever, schistosomiasis, filariasis, abscess and venereal disease 13 of the volunteers were recorded in the previous paper as having had some disturbance of health during or soon after their course of treatment of germanin. The 38 volunteers who have been under close observation during the

last few months have kept so well in health that Conson is now doubtful whether germanin did not play some part in the production of these illnesses. IV Y

HAWKING (Frank) Contribution on the Mode of Action of Germanin (Bayer 206) — *Ann. Trop. Med. & Parasit.* 1939 Mar 31 Vol. 33, No. 1 pp 13-19 [12 refs.]

The object of this paper is to describe *in vitro* experiments upon the trypanocidal action of germanin with a view to comparing the behaviour of this compound with that of the trivalent arsenicals and acriflavine. The trypanosomes used were the reviewer's strain of *T. rhodesiensis* and the same parasite made resistant to germanin by means of Jancsó's technique.

It was found that germanin had practically no trypanocidal action *in vitro* but that if normal trypanosomes are incubated with it *in vitro* and then washed and inoculated into mice they fail to infect. Germanin-fast trypanosomes do not lose their infectivity under these conditions. The amount of germanin absorbed by the trypanosomes *in vitro* as judged by ~~concentration~~ estimation, is small and no difference was detected between normal and resistant trypanosomes in this respect. IV Y

VERTHALER (R. W.) & BOWELL (A.) D. F. [Übung kleinster Germaninmengen im Kaninchenblut als Schutz gegen eine Infektion mit *Trypanosoma brucei*] — [The Significance of the Smallest Doses of Germanin in Rabbit Blood as a Protection against Infection with *T. brucei*] — *Arch. f. Schiffs- u. Trop. Hyg.* 1939 Apr Vol 43 No. 4 pp 149-160 With 5 figs.

Lang's method for the estimation of germanin in blood, as improved by Dangerfield, Gaunt, and Wormald, was examined by the present authors and found to be of value both in the case of plasma and serum. A number of parallel estimations made in the plasma and serum of different samples of blood did not give identical results sometimes the plasma values were a little higher than those of the serum and sometimes the reverse was the case.

Attention is drawn to the fact that the serum of small animals before the administration of germanin gives a certain amount of yellow colouration with the reagents. This is supposed to be due to amines produced in the blood by hydrolysis. The blank value (Blindwert) varies not only in different rats and rabbits, but also in the same animals on different occasions. The variation noticed in one rabbit on different days amounted to 0.72 mgm. per 100 gm. It follows, therefore that estimation of germanin by the method in question can only be accurate if the blank value is obtained shortly before the drug is given.

The authors give curves showing the amount of germanin found in the blood of rabbits at various periods from 5 minutes up to 10 days after the administration of 10 mgm 4.5 mgm 3.5 mgm. and 2.5 mgm. per kilo of body weight respectively. Having ascertained these values they then proceeded to inoculate a considerable number of rabbits with *T. brucei* at periods when the concentration of drug in the serum was estimated to be at levels falling as low as 1 mgm per 100 cc. All the rabbits were protected. [See also this *Bulletin* 1938, Vol. 35 p 714.] IV Y

VAN DEN BRANDEN (F) Etude de l'action des vapeurs de "Bayer 205" sur le rat blanc infecté de trypanosome (Brucei) [Study of the Action of the Vapour of Bayer 205 on Rats Infected with *T. brucei*].—*Ann Soc Belge de Méd Trop* 1938. Sept 30 Vol 18. No 3 pp. 515-522. With 1 fig

A description of the technique and apparatus used is given. The solutions vapourized consisted of 40 cc. of a 5 or 10 per cent solution of the drug. In all 14 animals were used in the experiments. In animals treated in this way before trypanosomes appeared in the blood the incubation period was prolonged for 4 to 15 days. No animal in which the parasites were present in the blood when treatment commenced were cured but temporary blood sterilization was obtained.

POP (A) & BUDAC (O) Le traitement du nagana et de la dourine expérimentale chez le rat par l'anticoman [The Treatment of Nagana and Dourine in the Rat by Anticomman].—*C R Soc Biol* 1938. Vol 129 No 34 pp 1229-1232.

The authors have repeated the work of SCHERN and ARTAGAVEYTIA ALLENDE on the trypanocidal action of anticoman [This substance is a mixture of synthalin bitartrate pancreas powder sodium phosphate tannic acid and bismuth subnitrate. It was found to be less toxic than synthalin alone. For previous work on this subject see this *Bulletin* 1936 Vol 33 p 204 and 1937 Vol 34 pp 192 553].

Pop and Budac administered the compound in suspension subcutaneously in rats infected with *T. brucei* and *T. equiperdum*. They found that its therapeutic action was but feeble maximal doses only sufficing to produce a certain proportion of cures. The prophylactic action was rather better but it was necessary to give the compound at the same time as the trypanosomes were injected. It is concluded that anticoman acts directly on the parasites and not by producing a hypoglycaemia—a conclusion reached some time ago by the reviewer and his colleagues who proved that the action of synthalin and allied compounds is direct [This *Bulletin* 1938 Vol. 35 p 342 and 343].

H Y

LAGODSKY (H) Atténuation de la virulence et du pouvoir pathogène d'un trypanosome (*T. annamense* chimio-résistant) après passage dans un organisme animal traité par Sb [Attenuation of the Virulence and Pathogenic Action of a Trypanosome (an Arsenio-Resistant Strain of *T. annamense*) after Passage through an Animal treated with Antimony].—*Bull Soc Path Exot* 1939 Jan. 11 Vol 32. No 1 pp 35-38

The observations recorded in this paper began with a rabbit which was given a preventive dose of a pentavalent antimonial viz. p aminophenylstibinate of methylglucamine followed 6 hours later by an injection of five million arsenic resistant *T. annamense*. On the ninth day the rabbit's blood was positive but it never exhibited any of the usual external signs of disease although the blood was always positive up to the time it was sacrificed on the 35th day.

On different occasions two guineapigs a mouse and Rabbit 2 were subinoculated from Rabbit 1. One of the guineapigs recovered

spontaneously and the blood of the others was cleared by a dose of tryparsamide. The mouse died of the infection in four days. Rabbit 2 became infected but resisted tryparsamide treatment. It likewise never developed external lesions up to the time it was killed. The strain was passed on through two other rabbits from which guinea pigs, mice and Rabbit 5 were inoculated. It apparently continued to exhibit the same characters.

The author concludes from this that although the prophylactic dose of the antimonial had no preventive action nevertheless it had a definite influence on the parasite in that it attenuated its virulence and its pathogenic power. H 1

VAN DEN BRANDEN (F) Recherche sur l'action de l'astreptine Meurice (P-aminophénol-sulfonamide) sur le *Trypanosoma Brucei*. [The Action of P Aminophenol Sulphonamide on *T. brucei*—*Ann. Soc. Belg. de Méd. Trop.* 1938. Dec. 31 Vol 18 No 4 pp 663-694]

The conclusion reached is that astreptine (p. aminophenol sulphonamide) has no action on rats infected with *T. brucei*. H 1

VAN DEN BRANDEN (F) Le sulfate d'ortho-oxy-quinoléine (chinosol-sunoxol) a-t-il une action in vitro sur des rats blancs infectés de *Trypanosoma "Brucei"*? [Has the Sulphate of Ortho-Oxy-Quinolone any Action on Rats infected with *T. brucei*?]—*Ann. Soc. Belg. de Méd. Trop.* 1938. Dec. 31 Vol 18. No. 4 pp. 695-698.

It was found that although this substance had no therapeutic action on rats infected with *T. brucei* it had some trypanocidal action in vitro. H 1

LATOUR (L) Résultats de l'application des doses médicamenteuses réfractées injectées à courts intervalles dans les trypanosomoses expérimentales. [The Results of the Administration of Fractional Doses of Drugs at Short Intervals in the Treatment of Experimental Trypanosomiasis.]—*Bull. Acad. Méd.* 1939 Apr 18. 103rd Year 3rd Ser Vol 121 No 14 pp. 550-556

Whilst the object of the experimenter and the clinician in the treatment of trypanosomiasis is the same i.e. the sterilization of the infection the conditions under which they work are different. The experimenter can take risks, but the clinician cannot run the risk of poisoning his patient.

The author has conducted a long series of experiments on mice with the objects, firstly of ascertaining whether the frequent administration of fractional doses is less toxic than the administration of the whole dose at once and secondly whether such a procedure is as effective from the therapeutic point of view. The toxicity experiments were performed on normal mice groups of at least 20 animals being used in each observation, and the therapeutic experiments on mice infected with *T. brucei*. The drugs employed were orsanine and the trivalent antimonial compound "anthiomaline".

In the toxicity experiments with orsanine it was found that when 4 cgm. was given at a single injection 11 of 20 mice died, but when this dose was divided into 3 fractional doses (1.0 1.5 and 1.5 cgm.

respectively) given at intervals of 4 and 3 hours only 5 of the 20 died. Similar results were obtained with the antimony compound

In the therapeutic experiments with orsanine it was found that a single dose of 3 mgm cured 100 per cent of mice.

Fractional doses of 1 mgm given 24 28 32 and 48 hours respectively after infection cured 27 of 28 mice three similar fractional doses given at the 24th 28th and 32nd hours cured all of 7 mice. When the interval between the injection of the fractional doses was increased to 24 hours the number of cures fell to 50 per cent and when it was still further increased to 48 or 72 hours the number of cures fell progressively to nil. The results with the antimonial, although not quite so clear-cut showed the same thing

From this work Launoy considers that a case is established for testing the method on man

MANNOZZI TORINI (Manno) Una tecnica per la separazione dei tripanosomi dal sangue circolante e preparazione di emulsioni di tripanosomi. [A Technique for the Separation of Trypanosomes from the Blood and the Preparation of an Emulsion of Trypanosomes.]—*Boll Istituto Sieroterap Milanese* 1938. Dec Vol 17 No. 12. pp.824-829 With 1 plate. German summary (6 lines)

The blood should be rich in trypanosomes and the author uses that of a guinea pig at 8-10 days after intraperitoneal injection of 4-5 cc. of infected blood. This gives 60-70 trypanosomes to 250-300 red cells.

Heart blood is diluted with twice its volume of a 1 in 10 mixture of 4 per cent citrate in 0.8 per cent saline. This is centrifuged for not less than 4 minutes at 1,800 revolutions per minute. The red and white cells are spun down but the trypanosomes remain in the supernatant fluid. This fluid is aspirated in one operation into a Pasteur pipette big enough to hold it all. It is then centrifuged at 4,000-5,000 r.p.m. for 4 minutes. This throws down all the trypanosomes and the clear supernatant fluid is pipetted off. The sediment though sometimes consisting of trypanosomes only more often contains a lower stratum of red cells. It is therefore suspended in 10-15 cc. 0.8 per cent. saline and spun for 3 minutes at 1,800 r.p.m. The red cells are sedimented and the trypanosomes remain in the supernatant fluid which is pipetted off and again spun as before at the high velocity.

The sediment consists only of trypanosomes and in saline forms the optimum material for the study of the physiology and biochemistry of the trypanosomes which are still alive.

Repetition of the process will eliminate all proteins and other substances contained in the plasma.

MANNOZZI TORINI (Manno) Studio di un fermento proteolitico nel tripanosoma della surra (Evansi) [Studies on a Proteolytic Ferment of *T. evansi*].—*Boll Istituto Sieroterap Milanese* 1938. Dec Vol 17 No 12. pp. 830-838. With 3 graphs. [13 refs.] English summary (9 lines)

The author has tested suspensions of *T. evansi* prepared by the method described above for proteolytic enzymes using casein gelatin and serum. Mixtures of 2 cc. casein (0.5 per cent.) 2 cc. acetic or phosphate buffer at various pH values 2 cc. emulsion of trypanosomes

and 0.25 cc. chloroform are incubated at 38° for 24 hours. The proteins are precipitated and the non-precipitable N is determined by the Kjeldahl method. The result is compared with a determination made on a control mixture without incubation.

It was found that proteolysis occurred especially at pH 5.9 and that the protease was inactivated by heat at 70°C. for 20 minutes. Activity with gelatin and serum proteins, though present was only slight

ROUBAUD (E.) & PROVOST (A.) Arrêt de croissance au cours d'infections à *Trypanosoma gambiense* chez la souris. [Arrest of Growth in Mice Infected with *T. gambiense*].—*Bull. Soc. Path. Exot.* 1939 Apr 4 Vol. 32 No. 4 pp 387-390 With 2 figs.

The strain used was isolated in Cameroons in 1934 and has since been maintained in guinea-pigs. In subinoculated mice the infections were chronic and irregular. In order to increase the virulence 4 young mice about 1 month old were inoculated with the guinea-pig strain on 2nd September 1938. One died on 4th October without exhibiting trypanosomes in its blood. A detailed history of the other 3 is given. Two died early in October but the third lived until 2nd February 1939. The most interesting feature about these mice is that their growth appeared to have been arrested. This was particularly noticeable in the case of the third animal, which lived until it was 6 months old (5 months after infection). It weighed only 9 gm. and there was great enlargement of the spleen, liver and thyroid.

The authors recall the infantism which Chagas attributed to infections with *T. cruzi* and wonder whether the phenomenon they have observed is related to it.

NICOLLE (P.) & SIMON (H.) La vitesse de sédimentation des hématies dans les trypanosomoses expérimentales du cobaye. [The Sedimentation Rate of the Red Cells in Experimental Trypanosomiasis of the Guinea-pig].—*Bull. Soc. Path. Exot.* 1939 Jan 11 Vol. 32 No. 1 pp 94-103

Having studied the sedimentation rate of the red cells in guinea-pigs infected with murine typhus, and having found that it was considerably increased at the beginning of the infection reaching its maximum and then decreasing rather quickly, it occurred to the authors that they might examine the phenomenon in guinea-pigs infected with *T. equiperdum*, *T. brucei* and *T. cruzi*. The technique used was that employed in the earlier work.

Details are given of observations on a considerable series of infected guinea-pigs. In all the animals the sedimentation rate was definitely increased. [Probably this is to be related to the auto-agglutination of red cells—a phenomenon well known in trypanosomiasis of man and animals. It was examined by the reviewer nearly 30 years ago—he found that the plasma and serum of infected man and animals contain an autoagglutinin which agglutinates the erythrocytes at low temperatures, but not at blood temperature. If the citrated blood of an infected rabbit is put in a watch glass and the temperature lowered to 5°C. or less, the red cells agglutinate strongly and sediment in a few minutes.]

FRENCH (M H) Studies in Animal Trypanosomiasis V Some Disturbances of the Host's Carbohydrate Metabolism Induced by *Trypanosoma congolense* and *Trypanosoma brucei*—*Jl Comp Path & Therap* 1938. Dec. Vol. 51 Pt 4 pp 269-281 [39 refs.]

The author has examined the sugar and lactic acid values and the CO_2 -capacity of the blood of oxen, sheep and donkeys infected with *T. congolense* and *T. brucei*. His conclusions are as follows—

(1) There is no gradual development of hypoglycaemia during *T. congolense* and *T. brucei* infections of large animals, but a sharp fall in the blood sugar level occurs shortly before death or crisis. In animals that are treated or recover without therapeutic aid, the blood sugar level returns to normal immediately crisis is passed.

(2) The CO_2 -capacity appears to fall as soon as the incubation period is over. A further drop usually occurs towards the end of the infection. It can be considered that an acidosis exists during infection and then becomes more pronounced as death approaches.

(3) Blood lactic acid values increase in the premortal stages and near crisis.

(4) A marked carbohydrate disturbance is caused in the host by pathogenic trypanosomes, but its mechanism has not yet been elucidated clearly.

BINNS (H R.) Observations on the Behaviour in Laboratory Animals of *Trypanosoma congolense* Broden, 1904—*Ann Trop Med & Parasit* 1938. Dec. 21 Vol. 32 No 4 pp 425-430

BLACKLOCK and YORKE [this *Bulletin* 1914 Vol 3 p 169] have drawn attention to the fallibility of conclusions regarding the pathogenicity of *T. congolense* drawn from a small number of inoculations, and to the danger of differentiating strains or species of trypanosomes on the results of such pathogenicity tests. The purpose of the present note is to record the results of the inoculation of small laboratory animals mainly white rats with *T. congolense* causing disease of cattle in the southern province of Nyasaland.

The results of inoculation of seven strains of this trypanosome into laboratory animals are summarized in a table which shows that there is a considerable difference in the susceptibility of individual animals to the parasites and that different strains of *T. congolense* appear to vary in pathogenicity. It is considered that the observations recorded in this communication give strong support to the conclusions of Blacklock and Yorke. II Y

DELIDIMITRIOU (G) Note sur le traitement de la trypanosomiase à congolense par le Surfen C Bayer [Note on the Treatment of *T. congolense* by Surfen C.]—*Ann Soc Belge de Méd Trop* 1938 Dec. 31 Vol. 18. No. 4 pp 539-542.

The author treated 270 cattle infected with *T. congolense* with 100 cc. of 2.5 per cent solution of Surfen C intramuscularly. Of the 253 animals which were re-examined 1 to 6 months later 28 (11 per cent.) were positive. As the author claims these results based on a single injection are hopeful. [See also this *Bulletin* 1935 Vol 32 p 686 1936 Vol. 33 p 663 1937 Vol 34 pp. 118 119 1938 Vol. 35 p 343.] II Y

VAN SACEGHEM (René) Note sur le traitement des trypanosomiases par le Surfen C chez les bovidés. [Note on the Treatment of Cattle Infected with Trypanosomes by Surfen C.]—*Ann. Soc. Belge de Méd. Trop.* 1939. Dec. 31 Vol. 18. No. 4 pp 699-703

The author draws certain conclusions from his observations. The dose given should not be less than 1 gm. per 100 kilo of weight and it should be given intramuscularly. Trypanosomes do not disappear from the blood for at least 24 hours after treatment. Five days later the blood should be re-examined, and if trypanosomes are present a second dose should be given. Cured animals can be re-infected. The drug acts better on *T. congolense* infections than on *T. vivax* infections.

In the author's opinion Surfen C is a drug of great value. It is preferable to tartar emetic and has the great advantage that it can be given intramuscularly. Unfortunately however its price is prohibitive. IF Y

SOLDINI (M) Procédé pratique et rapide de diagnostic expérimental de la dourine. [A Rapid and Practical Method of diagnosing Dourine.]—*Bull. Soc. Path. Exot.* 1939 Mar 8. Vol. 32. No 3 pp 334-341

After stressing the importance of dourine as a disease of Algerian horses Soldini discusses the various methods which are used for diagnosis in view of the difficulty in finding trypanosomes, i.e. the intrapalpebral reaction of Lanfranchi and Soma, the formal-gel reaction and the complement fixation test.

The method recommended by the author is the incision of the scrotal fluid from the genital lesions of the horse and, failing this, its blood into the testicles of a rabbit. The rabbit's testicles form an eminently suitable medium for the multiplication of *T. equiperdum* and lesions develop between the 4th and 8th days. IF Y

ZWIMER (Raymond L.) & CULBERTSON (James T) The Serum Potassium Level in Trypanosoma equiperdum Infection in Rats the Role of Potassium in Death from this Infection.—*Amer. J. Hyg.* 1939 Jan. Vol. 29 No. 1 Sect. C pp 7-12 With 1 fig [18 refs.]

The authors discuss the various theories which have been advanced to explain the deaths of rats infected with pathogenic trypanosomes and conclude that none of the three theories viz., the production of an endotoxin, the development of hypoglycaemia, or asphyxiation, affords an adequate explanation of the phenomenon. It seemed to the authors that there was a superficial similarity between the terminal spasms of rats infected with pathogenic trypanosomes and the spasms in fatal potassium poisoning and it was considered that possibly death in trypanosomal infections might result from an elevation of the serum potassium above the critical threshold. It was therefore decided to follow the potassium level of the serum of rats throughout the course of infection with *T. equiperdum* with a view to determining whether potassium could play a significant rôle as the cause of death in this infection. Experiments showed that, as a matter of fact the serum potassium level of rats dying of *T. equiperdum* is markedly increased, and that

this increase commenced about 24 hours before death. Accordingly, it is suggested that this elevated serum potassium is a significant factor in the cause of death. II Y

POINDEXTER (Hildrus A.) Relationship of Mononuclear Response to Resistance in Experimental Trypanosomiasis.—*Amer Jl Hyg* 1939 May Vol 29 No 3 Sect C pp 111-114

Young rats have more flexible mononuclear response to stimulation than older rats and this response is associated with a greater response to *T. equiperdum* and its products. A temperature above 41°C. kills or renders *T. equiperdum* avirulent *in vitro* or *in vivo* within 20 to 30 minutes. II Y

KOLMER (John A.) & RULE (Anna M.) Sulphanilamide in the Treatment of Experimental Trypanosomiasis of Rats.—*Proc Soc Experim Biol & Med* 1939 Jan Vol 40 No. 1 pp 77-79

The general conclusion reached in this work is that sulphanilamide either by intravenous or oral administration is ineffective in the treatment of *T. equiperdum* infections of rats. II Y

JAUFFRET (R.) Contribution à l'étude du surra des bovidés au Cambodge [Surra in Cambodia Cattle].—*Rec Méd 1^{re} Exot* 1939 Jan.-Mar Vol 12 No 1 pp 5-14

Blood examination of 4 668 cattle more than 8 years old revealed the fact that 5 per cent were infected with *T. evansi*. The infection was only discovered after antiplague vaccination and the appearance of trypanosomes always followed the febrile disturbance provoked by the vaccine. These observations show that cattle constitute the reservoir of *T. evansi*. Treatment by naganol gave good results [See also this *Bulletin* 1938 Vol. 35 p 330] II Y

PAYLOV (P.) & GUENEV (Chr.) Recherches sur un trypanosome (*Trypanosoma evansi* Steel 1885) trouvé dans le sang d'un cheval de la région de Bourgas en Bulgarie (Note préliminaire).—[A Trypanosome (*T. evansi*) found in a Horse in Bulgaria].—*Ann Parasit Humaine et Comparée* 1939 Mar 1 Vol. 17 No 2, pp 158-161 With 2 figs [16 refs]

The authors describe and figure a trypanosome found by them in a horse at Bourgas, Bulgaria which they identify as *T. evansi*. II Y

LLOVEROL (H.) Le sérum normal de cynocéphale (*Papio papio* Desm.) dans le traitement de la trypanosomiase expérimentale du mouton à *T. dimorphon* Laveran et Mesnil. [Cynoccephalus Serum in the Treatment of Experimental *T. dimorphon* Infections of Sheep].—*Bull Soc Path Exot* 1939 Mar 8 Vol. 32 No 3 pp 328-334

The author used 8 sheep in his experiments. All were inoculated subcutaneously with *T. dimorphon* Laveran and Mesnil isolated from a naturally infected sheep. Three of the animals were kept as controls.

and 5 were treated with the serum of a normal *Cynocephalus*. Protocols of the observations are set out at length.

The author concludes from his work that a single dose of 15 to 20 cc. of the serum given intravenously is able to produce sterilization of a sheep experimentally infected with *T. dimorphus*. He considers that he cured 2 of his 5 sheep. The serum, however, may produce serious and even fatal results in debilitated animals.

DUCA (Charles J.) Studies on Age Resistance against Trypanosome Infections II. The Resistance of Rats of Different Age Groups to *Trypanosoma lewisi* and the Blood Response of Rats Infected with this Parasite.—*Amer J Hyg* 1939 Jan. Vol 29 No. 1 Sect. C. pp 25-32 With 1 fig [12 refs]

The earliest investigators had observed that young rats suffered more intense and more frequently fatal infections from *T. lewisi* than did older animals. Casual observations by Duca on some hundreds of rats in the Department of Bacteriology at Columbia University revealed a higher mortality from *T. lewisi* to occur in suckling rats and it was decided to investigate the problem methodically.

After it had been established that rats of different ages differ in their resistance to *T. lewisi* an attempt was made to investigate the actual mechanism responsible for the age difference. The leucocyte response and the erythrocyte picture were studied in considerable detail. The following are the conclusions—

- "(1) There is a sharp difference in the resistance against *Trypanosoma lewisi* among rats of different ages. *T. lewisi* is markedly pathogenic for rats 25 days of age or younger and in them frequently causes death. Death because of *T. lewisi* infection occurs only rarely in rats more than 25 days old.
- "(2) Rats which survive a *T. lewisi* infection exhibit about the time of the crisis, a marked leucocytosis and a marked absolute monocytosis. This white cell response does not occur in rats which die from *T. lewisi* infection.
- "(3) Rats infected with *T. lewisi* exhibit a marked secondary anaemia. This is probably a major factor in the death of rats less than 25 days of age.

CULBERTSON (James T.) & KESSLER (Walter R.) Studies on Age Resistance against Trypanosome Infections III. Vaccination of Rats against *Trypanosoma lewisi* with Special Reference to the Response of Different Age Groups.—*Amer J Hyg* 1939 Jan. Vol 29 No 1 Sect. C pp. 33-43 [15 refs]

It was found that rats can be rendered completely resistant to *T. lewisi* by the repeated injection of formalized homologous antigen. Among mature rats a few injections given at intervals of several days sufficed to produce complete resistance to injections of large numbers of living parasites. Older rats respond considerably better than younger rats. They respond promptly with the production of agglutinin, and the titre of the agglutinin developed is roughly related to the degree of resistance shown against the living organisms. Sucklings manifest only feeble capacity to produce agglutinins, and some of the younger animals succumb to vaccination quite as readily as non-vaccinated rats of the same age.

CULBERTSON (James T) Studies on Age Resistance against Trypanosome Infections. IV The Activity of Germanin (Bayer 205) upon *Trypanosoma equiperdum* Infections in Rats of Different Age Groups.—*Amer Jl Hyg* 1939 Mar Vol. 29 No 2. Sect. C. pp 73-77 [12 refs.]

It is believed that many of the well-known chemotherapeutic substances require for their action upon an invading parasite the intervention of the cells of the host body. As in previous work [see above] the author has found that the reticulo-endothelial system of young rats is less effective in affording the body definite resistance against infections with certain species of trypanosome than is that of older rats. It appeared worth while performing an experiment to determine the comparative efficacy of germanin in the treatment of experimental *T. equiperdum* infections in rats of different age groups.

It was found that in nursing rats the organisms generally persist for 30 to 36 hours after injection of the drug whereas in older rats with an equal infection the parasites disappear within 15 hours. It is concluded that the difference is probably related to a difference in the phagocytic capacities of the cells of the rats of different age groups.

CULBERTSON (James T) Transmission of Resistance against *Trypanosoma lewisi* from a Passively Immunized Mother Rat to Young nursing upon her [Research Notes].—*Jl Parasitology* 1939 Apr Vol. 25 No. 2. pp 182-183

The experiments described in this note show that a normal mother rat, passively immunized after delivery against *T. lewisi* by intraperitoneal injection of the serum of a specifically immunized rat will afford resistance to young rats nursing upon her. It thus appears that the resistance naturally acquired by young rats from an immune mother is dependent upon the transfer to the young of an antibody identical with or similar to that found in the blood of the parent.

IV Y

CULBERTSON (James T) The Immunization of Rats of Different Age Groups against *Trypanosoma lewisi* by the Administration of Specific Antiserum *per os*. [Research Notes].—*Jl Parasitology* 1939 Apr Vol. 25 No 2 pp 181-182.

In previous work the author showed [see above] that the young of a rat immune to *T. lewisi* are also resistant to this parasite the resistance being acquired by the young largely after birth through the ingestion of the milk of the immune mother. The remarkable facility with which the young of all nursing ages acquired immunity led to an experiment to determine whether rats of different age groups could be protected against *T. lewisi* by the administration of a specific antiserum *per os*.

Rats of various ages, from 10 to 60 days were given *per os* 0.5 cc of specific antiserum per 10 gm. of body weight. The experiments showed that rats can be immunized against *T. lewisi* in this way throughout the usual nursing period (21 days) although late in this period with progressively less effectivity. Whether the intestine of older animals becomes impermeable to the antibody or develops the capacity to denaturize this antibody is as yet unknown.

IV Y

and 5 were treated with the serum of a normal *Cynocephalus*. Protocols of the observations are set out at length.

The author concludes from his work that a single dose of 15 to 20 cc. of the serum given intravenously is able to produce sterilization of a sheep experimentally infected with *T. dimorphum*. He considers that he cured 2 of his 5 sheep. The serum however may produce serious and even fatal results in debilitated animals. W Y

DUCA (Charles J.) Studies on Age Resistance against Trypanosome Infections. II. The Resistance of Rats of Different Age Groups to *Trypanosoma lewisi* and the Blood Response of Rats Infected with this Parasite.—*Amer J Hyg* 1939 Jan. Vol. 29 No. 1 Sect. C, pp. 25-32. With 1 fig. [12 refs.]

The earliest investigators had observed that young rats suffered more intense and more frequently fatal infections from *T. lewisi* than did older animals. CULBERTSON (James T) Phagocytosis of Trypan Blue in Rats of Different Age Groups.—*Arch. Pathology* 1939 Feb Vol. 27 No 2, pp. 212-217 With 1 fig

The work described in this paper was devised with the object of ascertaining whether the increased natural resistance against certain infections manifested by man and animals as they grow older may be related to an increasing reactivity of protective cells. It was hoped to find through the use of trypan blue whether the phagocytic function of these cells becomes more effective as the animals approach maturity.

In his experiments the author used a 1 per cent. suspension of trypan blue in distilled water on groups of rats 6 10 15 18, 23 40 and 60 days old, respectively. All the animals were kept on a standard diet. Half of them received an intraperitoneal injection of 0.1 cc. of the suspension of trypan blue per 10 gm. of body weight and the remainder twice this dose. Eighteen hours later all the rats were killed and the various tissues fixed and stained lightly with eosin.

Examination of the tissues revealed no significant difference in the phagocytic capacity of the cells of any of the organs of the various age groups, except the liver. In this organ, however, well marked and constant differences were observed. Not only did more Kupffer cells in the liver of the older rats contain particles of the dye, but larger numbers of particles were found within each phagocytosing Kupffer cell of the older animals. These points are brought out in a table and in photographs. The conclusions are as follows:—

There is a difference in capacity for phagocytic function between young and old rats, the Kupffer cells of nursing animals being less able to phagocytose particles of trypan blue than the Kupffer cells of older animals. This difference can be correlated with a gradually acquired resistance of rats against a natural blood flagellate (*Trypanosoma lewisi*) of this animal. It is suggested that the resistance which the rat naturally acquires against this parasite as it grows older is in part accounted for by a gradually acquired enhancement in the phagocytic capacity of the host's cells.

MAZZA (Salvador) et al. Investigaciones sobre la enfermedad de Chagas. Gobernación Chaco. A. La enfermedad de Chagas en la gobernación del Chaco [Chagas Disease Its Presence in the Chaco].—*Universidad Buenos Aires. Misión de Estudios de Patología Regional Argentina* Juwy 1939. Publicación No 40 pp. 1-150. With 104 illustrations.

Dr. Mazza in an introductory article mentions 68 human acute cases of Chagas disease seen in various parts of the Chaco and the finding of 184 *Triatoma infestans* positive among 506 collected from the houses. Of the 68 human patients, 7 were under 6 months of age, 11 between 1 and 2 years, 13 between 2 and 3 years, 12 between 5 and 10 years and after that a progressive diminution with age. 44 were under 10 years.

In a series of eight papers Dr. Mazza and his colleagues record cases seen in different parts of the Chaco country, all of them typical.

BRUMPT (E) Faits expérimentaux et cliniques concernant le mode de transmission de la maladie de Chagas ou trypanosomose américaine [Experimental and Clinical Facts concerning the Method of Transmission of Chagas Disease]—*C R Soc Biol* 1939 Vol 130 No 12 pp 1197-1200

It is now generally agreed that the usual mode of infection of the vertebrate with *T. cruzi* is by the infected excreta of the reduviid bugs. Various experiments have however from time to time been recorded suggesting that the bite of the bugs may sometimes be infective. Brumpt considers the criticisms which have been raised to such conclusions and records more recent observations of his own.

During his recent visit to Mexico (1933) he isolated a number of strains of *T. cruzi*. One of these was virulent to mice attempts to infect a young rat by the bite of 50 young nymphs the dejecta of which were infective for rats of the same age failed. Similar negative results were obtained in Brumpt's laboratory by DENECKE and VON HALLER.

ROMANA (C.) Reproduction chez le singe de la conjonctivite schizotrypanosomienne unilatérale. [Reproduction in the Monkey of Unilateral Trypanosomal Conjunctivitis].—*Bull Soc Path Exot.* 1939 Apr 4 Vol. 32, No. 4 pp 390-394 With 2 figs.

The author has reproduced in two monkeys the unilateral conjunctivitis, seen so commonly as an early sign of Chagas disease by depositing in the conjunctiva the infected faeces of *Rhodnius prolixus*. Signs appeared 10 days later and the clinical syndrome was similar to that observed in human patients. IF 1

RELAPSING FEVER AND OTHER SPIROCHAETOSSES

Prices of Abstracts in this Section

DELFT and RAFTI (p. 757) report on the presence of relapsing fever in Iran and state that the incidence is greater than has been generally believed. Clinically the course is often long and the infection resistant to treatment. The spirochaete, *S. persica* was studied and transmission experiments made with various species of tick. A suggested classification of the strains of relapsing fever spirochaetes is given based on their behaviour in guinea-pigs. WHEELER (p. 753) records a total of 138 cases in California in the 17 years since the disease was discovered there—nearly all the infections occurred in June–September and nearly half the total in July. He gives an account of transmission experiments—it was rare (less than 2 per cent) for the infection to pass through the egg to the larval stage of the tick, *O. hermsi*. Ticks might become infected directly by sucking the blood of other ticks. BOXÉ (p. 759) by experiments with *O. montana* on mice showed that the insect's salivary glands do not become infected. Injection of the faeces also failed to convey the disease—the infecting agent is considered to be the coxal fluid. The same author offers further experimental evidence that *S. danovus* can penetrate the barrier between the haemocoel and the coxal glands and appear in the coxal fluid whereas foreign corpuscles, bacteria, etc. do not. He tested the hereditary transmission of the same spirochaete by *O. montana*—the results varied but on the whole tended to support the view that infection is transmitted to the next generation by spirochaetes *as such*. Duration of infectivity of *O. furcata* was investigated by FRANCIS (p. 760). He found that Texan relapsing fever was transmitted by their bite after starvation for 5 years, and by others which had been fed once only in 6½ years. The coxal fluid was not infective. Hereditary transmission via eggs of infected ticks was observed. The Texan strain in man did not respond to neocarsphenamine. Bed bugs after feeding on infected patients, themselves infected mice which ingested these insects.

KIRK (p. 761) made a laboratory study by cultivation and animal inoculation, of a louse transmitted spirochaete from Abyssinia. Attempts to infect ticks especially *O. sergryi* with this strain were completely unsuccessful although this tick is an important vector in Abyssinia. CHUNG and WEI (p. 763) investigated the mechanism of transmission of relapsing fever by the louse to a general paralytic

subjected to pyretotherapy. The authors findings support the view that the bodies of the insects are infective whereas their bite is not. MORISSETTA (p 763) found that the rat-mite *Liponyssus* would retain infection with spirochaetes for 7 days but that it does not transmit it by the bite nor is the infection passed to the next generation.

CHUNG and CHANG (p 763) studied clinically 337 patients in the Peiping Hospital between 1921-37. Males greatly preponderated 6 to 1 in corrected figures. The disease occurs in the district all the year round but the incidence rises from December to reach a climax in April. A detailed analysis of the symptoms is given. DIGONNET and MATHIS (p 765) describe the case of a woman two months pregnant infected by relapsing fever (tick borne) in spite of threatened abortion pregnancy went to term. A method for facilitating diagnosis is described by SNOOKS (p 765) by which in the case of blood the cells are dissolved out by a haemolytic system and in the case of tissues by a cytolytic agent. He recommends 10 per cent sodium taurocholate with methylene blue whereby the spirochaetes are stained and so though few in number are easily seen.

LOBENWICKA (p 766) notes the increase of cells lymphocytes mainly, together with increase of pressure in the cerebrospinal fluid of African relapsing fever patients. Meningeal symptoms are far from uncommon in African relapsing fever—a fact to be borne in mind in regions where trypanosomiasis exists.

DI BENEDETTO (p 766) gives a clinical review of 193 cases of relapsing fever observed in Italian East Africa but does not mention whether the vector in this district is a louse or a tick. In speaking of treatment arsenicals seem to be essential for success though he regards their combination with auxillaries such as insulin, and liver extract as more beneficial than the first alone. Figures to support his thesis are not however given.

HAWKING (p 767) has tested the reaction of strains of relapsing fever spirochaetes to chemicals—arsenic, antimony, gold and acriflavine preparations—using methods previously employed with trypanosomes. Details are given in a table. The work of André SERGENT (p 768) on relapsing fever in Algeria has already been referred to [this *Bulletin* 1939 Vol. 36 p 108] the article noted here is an *In Memoriam* issue.

DELPA (L.) & RAYSI (A) Sur la fièvre récurrente sporadique en Iran. Contribution à l'étude expérimentale de *Spirochaeta persica* Dschunkowsky, 1913 [Sporadic Relapsing Fever in Iran. A Contribution to the Experimental Study of *Spirochaeta persica* Dschunkowsky, 1918.]—*Ann. Parasit. Humaine et Comparée* 1939 Jan 1 Vol. 17 No 1 pp 45-61 With 1 chart & 3 figs.

The authors mention the frequent occurrence of cases of persistent and irregular fever resistant to quinine occurring in the region to the East of Teheran. During the summer of 1937 whilst examining only people more or less attached to the laboratory 5 of such cases were found to be typical infections of relapsing fever which suggests that the disease is much more common in Iran than was previously supposed.

All these 5 cases occurred in the village of Hessarek and all the patients had been exposed to the bites of *Ornithodoros tholozani* (*O. papillipes*). The course of the disease is long and often serious.

One of the patients had four febrile attacks in 17 days and a fifth 13 days later. After being under observation for 45 days, the blood of this patient was still infective to rabbits. Two of the cases responded to treatment with novarsenobenzol, but in two others the course of the disease seemed to be unaffected.

An experimental study was made of the spirochaete *S. persica* isolated from these cases. The results of inoculation experiments show that rats and rabbits are quite as susceptible to infection as guinea-pigs. Splenectomized dogs are rather less susceptible, also sheep and in the latter species spirochaetes were never seen in the blood. The brain remained infective up to 268 days in the case of the rat, 24 to 25 days in dogs and 8 to 73 days in sheep. In the rat the incubation period may be as long as 20 days, double that in the guinea-pig, but otherwise the infection follows the same course as in guinea-pigs and rabbits.

Three rabbits and a guinea-pig that had recovered from infection 2 to 7½ months previously were found to be immune against reinfection.

Transmission experiments were made with *Ornithodoros tholozani*, *O. lahorensis* and *Hyalomma dromedarii* which were allowed to feed on infected animals and subsequently the following stage fed on normal animals. *O. lahorensis* and *H. dromedarii* gave negative results but in the case of *O. tholozani* a nymph infected after the first moult produced infection by its bite 116 days later and in the adult stage a second infection after 458 days. A female tick infected a rabbit by its bite 371 days after feeding on an infected rat and after 328 days it had laid eggs from which hatched infected larvae.

The authors conclude with a general discussion on the various strains of relapsing fever spirochaetes occurring in Central Asia, and classify them as follows according to their behaviour in guinea-pigs.

A. Strains highly pathogenic to guinea-pigs, often fatal, with splenomegaly even to rupture of the spleen.

(a) *S. uzbekistanica* Pilgoul 1928 (Mortality 100 per cent.)

(b) Strain Stalinbad. Pavlovsky and Brumpt 1934 (Mortality 71 per cent with haemoperitoneum)

(c) Strains S5 and S11 Adler *et al* 1937. Mortality 37 & 48 per cent splenomegaly and frequent rupture of the spleen.

B. Strains producing a more or less intense blood infection but without any appreciable lesions and ending in recovery.

refe

A total of 138 cases of infection have been recorded which nearly all occurred between June and September July being the month with most cases (62)

The infection has been transmitted to white mice monkeys and human subjects by the bites of infected ticks and it has been shown that the infection passes through the egg to the larva in less than 2 per cent. of about 600 tested. Seven rhesus monkeys were exposed to the bites of 17 infected ticks but only one monkey developed the infection spirochaetes appearing after an incubation period of 16 days. During these experiments no faeces or coxal fluid were excreted by the ticks whilst feeding and therefore the infection must have been introduced by means of the mouth parts presumably from the salivary glands. It was also noted that in nature ticks sometimes suck blood from other ticks and in this way infection might be transmitted from one tick to another without the presence of a mammalian host.

Seven human subjects were exposed to the bites of infected ticks and one of them bitten by 2 adults developed the disease after an incubation period of 7 days and showed three febrile attacks spirochaetes being found in the first two of them. Although this patient had received a systematic treatment with neosalvarsan bismuth and trypanamide for nearly 17 months this did not seem to alter the course of the infection with relapsing fever. BONÉ (G) Mode de transmission du spirochète de Dutton par les *Ornithodoros moubala* [The Method of Transmission of *Spirochaeta duttoni* by *Ornithodoros moubala*].—C R Soc Biol 1938. Vol 129 No 32 pp 901-903

The author has fed on various mice 337 nymphs infected both hereditarily and by feeding on infected blood and also 10 adults of *Ornithodoros moubala* without ever producing infection with *Spirochaeta duttoni*. It is concluded therefore that the salivary glands do not become infected. Negative results were also obtained by the injection of the tick's faeces, and the author considers that the coxal fluid alone is responsible for the production of infection. E H

BONÉ (G) L'infection des *Ornithodoros moubala* par le spirochète de Dutton [The Infection of *Ornithodoros moubala* with *Spirochaeta duttoni*].—C R Soc Biol 1938 Vol 129 No 32 pp 903-905

The author has made dark ground examinations of the contents of *O. moubala* fed on mice infected with *S. duttoni*. The spirochaetes were found to enter the coelomic fluid and there multiply by simple fission. It was also noted that when ticks became fully engorged the spirochaetes entered the coelomic fluid much more readily than in ticks only partially engorged. Also an increase in the number of spirochaetes in this fluid was noted when infected ticks were fed on normal mice which is supposed to be due to the liberation of spirochaetes from the wall of the gut as a result of the passage of fluid from the newly ingested blood.

Ticks were infected artificially by the injection of spirochaetes into their coelomic cavity and showed the multiplication of these organisms and the coxal fluid became infective. Also the same augmentation in numbers was observed when they were fed on normal mice.

One of the patients had four febrile attacks in 17 days and a fifth 13 days later. After being under observation for 45 days the blood of this patient was still infective to rabbits. Two of the cases responded to treatment with novarsenobenzol, but in two others the course of the disease seemed to be unaffected.

An experimental study was made of the spirochaete, *S. persica* isolated from these cases. The results of inoculation experiments show that rats and rabbits are quite as susceptible to infection as guinea-pigs. Splenectomized dogs are rather less susceptible also sheep and in the latter species spirochaetes were never seen in the blood. The brain remained infective up to 268 days in the case of the rat 24 to 25 days in dogs and 8 to 73 days in sheep. In the rat the incubation period may be as long as 20 days double that in the guinea-pig, but otherwise the infection follows the same course as in guinea-pigs and rabbits.

Three rabbits and a guinea-pig that had recovered from infection 2 to 7½ months previously were found to be immune against reinfection.

Transmission experiments were made with *Ornithodoros tholozani*, *O. lahorensis* and *Lipalomma dromedarii* which were allowed to feed on infected animals and subsequently the following stage fed on normal animals. *O. lahorensis* and *L. dromedarii* gave negative results, but in the case of *O. tholozani* a nymph infected after the first moult produced infection by its bite 116 days later and in the adult stage a second infection after 458 days. A female tick infected a rabbit by its bite 371 days after feeding on an infected rat and after 323 days it had laid eggs from which hatched infected larvae.

The authors conclude with a general discussion on the various strains of relapsing fever spirochaetes occurring in Central Asia, and classify them as follows according to their behaviour in guinea-pigs.

- A. Strains highly pathogenic to guinea-pigs often fatal, with splenomegaly even to rupture of the spleen.

WHEELER (Charles M.) Relapsing Fever in California. Attempts to transmit Spirochaetes of California Relapsing Fever to Human Subjects by Means of the Bite of the Vector *Ornithodoros hermsi* Wheeler.—*Amer J Trop Med* 1938 Nov Vol. 18, No. 6. pp. 641-656 With 1 map 3 figs & 1 plate. [12 refs.]

A summary of the case distribution of relapsing fever in California since its discovery in 1921 up to 1937 together with an account of transmission experiments with its vector *Ornithodoros hermsi*

A total of 138 cases of infection have been recorded which nearly all occurred between June and September July being the month with most cases (62)

The infection has been transmitted to white mice monkeys and human subjects by the bites of infected ticks and it has been shown that the infection passes through the egg to the larva in less than 2 per cent of about 600 tested. Seven rhesus monkeys were exposed to the bites of 17 infected ticks but only one monkey developed the infection spirochaetes appearing after an incubation period of 16 days. During these experiments no faeces or coxal fluid were excreted by the ticks whilst feeding and therefore the infection must have been introduced by means of the mouth parts presumably from the salivary glands. It was also noted that in nature ticks sometimes suck blood from other ticks and in this way infection might be transmitted from one tick to another without the presence of a mammalian host

Seven human subjects were exposed to the bites of infected ticks and one of them bitten by 2 adults developed the disease after an incubation period of 7 days and showed three febrile attacks spirochaetes being found in the first two of them. Although this patient had received a systematic treatment with neosalvarsan bismuth and trypanamide for nearly 17 months this did not seem to alter the course of the infection with relapsing fever E H

BOVÉ (G) Mode de transmission du spirochète de Dutton par les *Ornithodores moubata* [The Method of Transmission of *Spirochaeta duttoni* by *Ornithodorus moubata*]—*C R Soc Biol* 1938 Vol 129 No 32 pp 901-903

The author has fed on various mice 337 nymphs infected both hereditarily and by feeding on infected blood and also 10 adults of *Ornithodorus moubata* without ever producing infection with *Spirochaeta duttoni*. It is concluded therefore that the salivary glands do not become infected. Negative results were also obtained by the injection of the tick's faeces and the author considers that the coxal fluid alone is responsible for the production of infection E H

BOVÉ (G) L'infection des *Ornithodores moubata* par le spirochète de Dutton [The Infection of *Ornithodorus moubata* with *Spirochaeta duttoni*]—*C R Soc Biol* 1938 Vol 129 No 32 pp 903-905

The author has made dark ground examinations of the contents of *O moubata* fed on mice infected with *S duttoni*. The spirochaetes were found to enter the coelomic fluid and there multiply by simple fission. It was also noted that when ticks became fully engorged the spirochaetes entered the coelomic fluid much more readily than in ticks only partially engorged. Also an increase in the number of spirochaetes in this fluid was noted when infected ticks were fed on normal mice which is supposed to be due to the liberation of spirochaetes from the wall of the gut as a result of the passage of fluid from the newly ingested blood.

Ticks were infected artificially by the injection of spirochaetes into their coelomic cavity and showed the multiplication of these organisms, and the coxal fluid became infective. Also the same augmentation in numbers was observed when they were fed on normal mice.

The author is of the opinion that his observations are in favour of a simple multiplication of the spirochaete in the body of the tick, without any other cycle of development

BOAS (Georges) L'excrétion des spirochètes de Dutton chez *Ornithodoros moubata* [The Excretion of *Spirochaeta duttoni* in *Ornithodoros moubata*]—C R Soc Biol 1909 Vol. 130 No. 1 pp 84-83 E H

A continuation of a previous note on the subject [See above.] The author has now investigated the problem of the presence of spirochaetes in the coxal fluid of infected *Ornithodoros*. Suspensions of sheep red cells, of bacteria, or of spirochaetes were injected into the haemocoel of different ticks and in some instances coxal fluid was emitted whilst the tick was being injected. In other cases the ticks were afterwards fed on mice and the coxal fluid collected. In both groups, spirochaetes were the only elements to appear in the coxal fluid, showing that there is a barrier between the haemocoel and the coxal glands. Consequently the spirochaetes must penetrate through this barrier in order to get into the cavity of the coxal glands.

BOAS (G) La transmission héréditaire du spirochète de Dutton à *Ornithodoros moubata* [The Hereditary Transmission of *Spirochaeta duttoni* in *Ornithodoros moubata*]—C R. Soc Biol 1930 Vol. 130 No 1 pp 86-87 E H

The author has examined the contents of eggs laid by *Ornithodoros moubata* fed on mice infected with *Spirochaeta duttoni*. In one case 40 eggs were examined without finding a single spirochaete but in a second experiment 3 females laid eggs which all contained spirochaetes. In a third experiment these same females laid eggs in which spirochaetes could not be found. In view of the fact that some of the eggs contain spirochaetes the author assumes that in ticks the infection is transmitted to the next generation by spirochaetes as such and not by any other stage.

Only 2 out of 7 mice injected with 5 to 100 of these eggs became infected, which the author considers may have been the result of the virulence of the spirochaetes being attenuated, or of their being affected by the coating of egg substance.

FRANCIS (Edward) Longevity of the Tick *Ornithodoros turicata* and of *Spirochaeta recurrentis* within this Tick.—Public Health Rep 1929 Dec 23 Vol. 53 No 51 pp 2220-2241 With 3 charts & 9 figs (8 on 3 plates) [20 refs] E H

A valuable summary of laboratory observations extending over 7 years upon 119 naturally infected *Ornithodoros turicata* collected in caves in Texas in 1931 and upon the survival of relapsing fever spirochaetes within these ticks for 6½ years. The ticks were collected from caves and overhanging ledges in various parts of Texas and naturally occurred in powdery dust or sand. All were fed on arrival in 1931 on two normal rhesus monkeys both of which became infected with relapsing fever. These ticks were kept in a corner of the laboratory in Washington from which steam heat

was excluded. Of the original 119 ticks 64 survived starvation for 3 years, 35 for 4 years and 13 for 5 years. They were tested as follows

12 ticks starved 3 years infected a monkey, and became group A	
11	4 B
13	5 C
5 group A ticks fed once in 6 years failed to infect	
5 " B	6½ years infected a monkey

Hereditary transmission of the infection to the next generation of ticks was obtained through eggs from naturally infected ticks and also from those artificially infected

Bed bugs *Cimex lectularius* if fed on blood containing spirochaetes were found to produce infection in 4 out of 8 mice which ingested these bugs. White mice readily attack and eat bed bugs therefore this is a way in which the infection might be transmitted. Eight lots of bugs also ingested blood containing *Spirillum minus* and were subsequently eaten by mice but none of them showed any signs of infection. Negative results were also obtained in attempts to infect mice by feeding them with lice *Pediculus longiceps* collected from infected monkeys. Although spirochaetes were not found in monkey lice during their first 16 days of subsistence on an infected monkey, they were demonstrated daily after the 17th day but these infected lice failed to infect a monkey on which 1,550 of them were liberated.

Various observations were made on the biology and life history of *O. turicata*. Spirochaetes were never found in the coxal fluid of infected ticks when examined by dark field and white mice inoculated with the fluid remained negative. The ticks are very resistant to moisture and continuous immersion in distilled water for a week had no ill effects.

Rhesus monkeys were found to be very susceptible to this relapsing fever and the incubation period averaged 4½ days for the first appearance of spirochaetes in the blood and 5½ days to the first onset of fever. Two monkeys out of eight succumbed to the disease and those which recovered did not show immunity to second attacks, 9 months to a year after the original infection.

The author includes useful observations on the methods of feeding ticks on animals.

Finally it is noted that neosarsphenamine failed to show any specific therapeutic value in three human cases infected with this Texas strain of relapsing fever

E H

KIRK (R.) A Laboratory Study of Abyssinian Louse-borne Relapsing Fever—*Ann Trop Med & Parasit* 1938. Dec. 21 Vol. 32. No 4 pp 339-356 With 1 text fig & 4 figs on 1 plate [39 refs.]

An interesting laboratory study of a strain of relapsing fever of Abyssinian origin, isolated from cases occurring in the Sudan in which the louse was incriminated as the vector

The length of the spirochaetes was found to average 18µ. Attempts to culture them on Yuan Po's and many other media gave completely negative results, but excellent cultures were obtained in a modified Noguchi medium prepared as follows—Under sterile conditions half-an-inch of egg albumen was pipetted into 5"×½" test tubes and then coagulated at 80°C. Then the tubes were filled to within 1½" from the top with fresh ascitic fluid. The tubes were inoculated with

The author is of the opinion that his observations are in favour of a simple multiplication of the spirochaete in the body of the tick without any other cycle of development.

Boxé (Georges) L'excretion des spirochètes de Dutton chez *Ornithodoros moubata* [The Excretion of *Spirochaeta duttoni* in *Ornithodoros moubata*]—C R Soc Biol 1939 Vol. 130 No. 1. pp. 84-85 E H

A continuation of a previous note on the subject. [See above.] The author has now investigated the problem of the presence of spirochaetes in the coxal fluid of infected *Ornithodoros*.

Suspensions of sheep red cells of bacteria or of spirochaetes, were injected into the haemocoel of different ticks and in some instances coxal fluid was emitted whilst the tick was being injected. In other cases the ticks were afterwards fed on mice and the coxal fluid collected. In both groups, spirochaetes were the only elements to appear in the coxal fluid showing that there is a barrier between the haemocoel and the coxal glands. Consequently the spirochaetes must penetrate through this barrier in order to get into the cavity of the coxal glands.

Boxé (G.) La transmission héréditaire du spirochète de Dutton chez *Ornithodoros moubata*. [The Hereditary Transmission of *Spirochaeta duttoni* in *Ornithodoros moubata*]—C R. Soc Biol 1939 Vol. 130 No. 1 pp. 83-87 E H

The author has examined the contents of eggs laid by *Ornithodoros moubata* fed on mice infected with *Spirochaeta duttoni*. In one case 40 eggs were examined without finding a single spirochaete but in a second experiment 3 females laid eggs which all contained spirochaetes. In a third experiment these same females laid eggs in which spirochaetes could not be found. In view of the fact that some of the eggs contain spirochaetes the author assumes that in ticks the infection is transmitted to the next generation by spirochaetes as such, and not by any other stage.

Only 2 out of 7 mice injected with 5 to 100 of these eggs became infected which the author considers may have been the result of the virulence of the spirochaetes being attenuated, or of their being affected by the coating of egg substance.

Francis (Edward) Longevity of the Tick *Ornithodoros turicata* and of *Spirochaeta recurrentis* within this Tick.—Public Health Rep 1938 Dec 23 Vol 53 No 51 pp 2220-2241 With 3 charts & 8 figs (8 on 3 plates) [20 refs.] E H

A valuable summary of laboratory observations extending over 7 years upon 119 naturally infected *Ornithodoros turicata* collected in caves in Texas in 1931 and upon the survival of relapsing fever spirochaetes within these ticks for 8½ years.

The ticks were collected from caves and overhanging ledges in various parts of Texas and usually occurred in powdery dust or sand. All were fed on arrival in 1931 on two normal rhesus monkeys both of which became infected with relapsing fever. These ticks were kept in a corner of the laboratory in Washington from which steam heat

was excluded. Of the original 119 ticks 64 survived starvation for 3 years 35 for 4 years and 13 for 5 years. They were tested as follows

12 ticks starved 3 years	infected a monkey and became group A	
11	4	B
13	5	C
5 group A ticks fed once in 6 years	failed to infect	
5 B	6½ years	infected a monkey

Hereditary transmission of the infection to the next generation of ticks was obtained through eggs from naturally infected ticks and also from those artificially infected

Bed bugs, *Cimex lectularius* if fed on blood containing spirochaetes were found to produce infection in 4 out of 8 mice which ingested these bugs. White mice readily attack and eat bed bugs therefore this is a way in which the infection might be transmitted. Eight lots of bugs also ingested blood containing *Spirillum minus* and were subsequently eaten by mice but none of them showed any signs of infection. Negative results were also obtained in attempts to infect mice by feeding them with lice *Pedicinus longiceps* collected from infected monkeys. Although spirochaetes were not found in monkey lice during their first 16 days of subsistence on an infected monkey they were demonstrated daily after the 17th day but these infected lice failed to infect a monkey on which 1,550 of them were liberated.

Various observations were made on the biology and life history of *O. turicata*. Spirochaetes were never found in the coxal fluid of infected ticks when examined by dark field and white mice inoculated with the fluid remained negative. The ticks are very resistant to moisture and continuous immersion in distilled water for a week had no ill effects.

Rhesus monkeys were found to be very susceptible to this relapsing fever and the incubation period averaged 4½ days for the first appearance of spirochaetes in the blood and 5½ days to the first onset of fever. Two monkeys out of eight succumbed to the disease and those which recovered did not show immunity to second attacks 9 months to a year after the original infection.

The author includes useful observations on the methods of feeding ticks on animals.

Finally it is noted that neoarsphenamine failed to show any specific therapeutic value in three human cases infected with this Texas strain of relapsing fever.

KIRA (R.) A Laboratory Study of Abyssinian Louse-borne Relapsing Fever.—*Ann Trop Med & Parasit* 1938 Dec. 21 Vol. 32. No 4 pp 339-356. With 1 text fig & 4 figs. on 1 plate [39 refs.]

An interesting laboratory study of a strain of relapsing fever of Abyssinian origin isolated from cases occurring in the Sudan in which the louse was incriminated as the vector.

The length of the spirochaetes was found to average 18μ. Attempts to culture them on Yuan Po's and many other media gave completely negative results but excellent cultures were obtained in a modified Noguchi medium prepared as follows.—Under sterile conditions half an-inch of egg albumen was pipetted into 5 × ½ test tubes and then coagulated at 80°C. Then the tubes were filled to within 1½ from the top with fresh ascitic fluid. The tubes were inoculated with

3-5 drops of blood containing spirochaetes and incubated at 37°C. The organisms grew very rapidly and subcultures were made every 2-4 days. One strain was passed through 12 subcultures without any diminution in virulence.

White rats rabbits, guineapigs and the ordinary black and brown wild rats were all insusceptible but white mice were readily infected from human cases spirochaetes appearing 12-24 hours after inoculation always present after 48 hours, and generally disappearing on the third day. Gerbilles were also susceptible.

Subinoculations from mouse to mouse were unsuccessful and passage through monkeys did not enhance the virulence.

The common grey monkey of the Sudan (*Cercopithecus sabarus*) was susceptible, and usually showed one relapse resembling the course in human beings. The strain was maintained in these animals for three passages. Spirochaetes were found in the haemocoel fluid of lice from infected persons, and a monkey was infected by rubbing some of the contents of a single louse on to the shaved abdomen of a splenectomized animal. This monkey died 12 days later with its blood swarming with spirochaetes and was the only one to die in the first paroxysm of relapsing fever. It is suggested that the disease acquired from the louse is more virulent than that produced by blood inoculation.

Evidence of immunity was found in infected animals but several antigenic variants were present. In monkeys splenectomy was found to influence the course of the first infection but had no effect on acquired immunity. In mice, splenectomy had no effect, probably owing to the fact that with very mild infections, the reserves of the reticulo-endothelial system are sufficient to mask any effects of splenectomy.

No evidence of latent or residual infections was found in mice and gerbilles after recovery.

The Abyssinian strain of relapsing fever evidently resembles in its general features other members of the North African group of louse-borne strains.

KIRA (R) The Non-Transmission of Abyssinian Louse-borne Relapsing Fever by the Tick *Ornithodoros savignyi* and Certain Other Blood-sucking Arthropods.—*Ann Trop Med & Parasit* 1938 Dec 21 Vol 32 No 4 pp 357-365. [34 refs.]

A record of experiments with an Abyssinian strain of louse-borne relapsing fever [see above p. 761] to determine whether it could be transmitted by other blood-sucking Arthropods.

Special attention was paid to the possibility of *Ornithodoros savignyi* as it has been cited as an important vector of relapsing fever in Abyssinia. The ticks were allowed to feed on either infected persons or animals and then after varying periods attempts were made to infect susceptible animals by the bite of these ticks, by the inoculation of coval fluid, and finally by the inoculation of their total contents. The results of these experiments were entirely negative and in addition spirochaetes were never found by dark ground examination of the coval fluid or in stained smears of the contents of the ticks. A single experiment with *Argas persicus* with six weeks interval between the infective meal and the inoculation of the ticks contents into mice, also gave negative results.

The examination of lice *Pediculus* found on infected monkeys showed the presence of abundant spirochaetes in smears of the lice even when no blood cells were noticed but all attempts to produce infection by the inoculation of the contents of these lice into a splenectomized monkey and gerbilles were uniformly negative.

CHUNG (Huei Lan) & WEI (Yu-Lan) Studies on the Transmission of Relapsing Fever in North China. II Observations on the Mechanism of Transmission of Relapsing Fever in Man.—*Amer J Trop Med* 1938 Nov Vol 18 No 6 pp 661-674 With 2 figs [13 refs]

A record of experiments on the transmission of the Chinese strain of *Spirochaeta recurrentis* performed on 6 normal subjects and 4 patients with general paralysis of the insane

Five subjects were exposed to the bites of large numbers of human lice which were known to be infected with the spirochaete but no signs of infection were observed When four lice infected 12 days previously were ground up in saline and this emulsion was placed on the skin of the forearm of a man who had just been bitten in the same place by normal lice this patient became infected with relapsing fever after 11 days incubation period Similar positive results were obtained by the introduction of the contents of body lice into the conjunctiva in two out of three patients exposed to infection the incubation period being 8 days.

Various attempts to infect patients by placing the contents of infected lice in the mouth gave uniformly negative results In one experiment the faeces of 100 lice collected daily 7 to 12 days after an infective feed were instilled on to the excoriated skin of a volunteer but no fever was observed during six weeks.

The results of these experiments support the view that the bites of infected lice are innocuous, and that the disease is contracted through crushing infected lice on the skin or introducing the infective material on to the conjunctivae.

MORISITA (T) Transmission Experiments on Relapsing Fever with Tropical Rat-Mite, *Liponyssus* sp.—*Japanese J Experm Med* 1938 Dec. 20 Vol. 16 No 6 pp 551-558

The author found that mites (*Liponyssus* sp.) collected from mice infected with spirochaetal relapsing fever (strain not stated) retained the infection up to seven days. Transmission was never obtained by the bites of these mites but only by the inoculation of the ground up contents. Moreover the eggs and larvae from these mites never contained spirochaetes.

CHUNG (Hui Lan) & CHANG (F C.) Relapsing Fever Clinical and Statistical Study of 337 Cases.—*Chinese Med J* 1939 Jan Vol. 55 No 1 pp 6-33 With 3 charts [16 refs.]

A useful clinical and statistical study of 337 in patients suffering from relapsing fever observed in the Peiping Union Medical College Hospital from 1921 to 1937 In every instance the diagnosis was confirmed by finding *Spirochaeta recurrentis* in the blood.

The sex distribution was 1 female to 17 males, and even after correction for ratio of admissions, was 1 female to 6 males probably owing to the fact that most of the patients contracted the disease in army camps poor-houses and small inns where the population was exclusively male.

The disease is endemo-epidemic in Peiping and occurs in all months of the year. The incidence is lowest in autumn, begins to rise in December and reaches its climax in April and May after which it declines.

The symptoms of these 337 patients are given in the following table.

Symptoms	No. of cases	Percent	Symptoms	No. of cases	Percent.
Sudden onset	307	91.5	Sweating	92	27.3
Fever	326	96.8	Scanty urination	85	25.2
Headache or dizziness	257	76.2	Abdominal pain	64	19.0
Chills or chilliness	215	72.7	Thirst	60	17.8
Anorexia	233	69.2	Auditory disturbance	47	14.0
General aching	198	58.8	Diarrhoea	47	14.0
Constipation	159	47.4	Visual disturbance	35	10.4
Cough	139	41.2	Epigastric pain	32	9.5
Prostration	124	36.8	Chest pain	18	4.8
Nausea	100	29.7	Metemesis	8	1.5
Vomiting	98	29.1	Convulsion	2	0.6
Epistaxis	92	27.3	Haematemesis	1	0.3

In most cases the incubation period was 5 to 11 days. The onset was generally sudden, the first symptoms being fever, chilliness, headache and pain in muscles and bones, associated with anorexia. The number of febrile attacks without treatment seems to be 3 to 5 and the duration of each varies from 4 to 10 days with an average of 7 days. In 74 patients the first remission varied from 3 to 16 days, the average being 7.1 days.

Splenomegaly was observed in 69.2 per cent, and enlargement of the liver in 40.7 per cent of the patients. Jaundice occurred in 29.4 per cent, haemorrhagic skin rash in 34.7 per cent, general glandular enlargement in 18 per cent, some patients had cerebral symptoms. Pneumonia occurred in 5 per cent, and was a very serious complication, accounting for 8 out of 21 deaths in this series.

The blood was examined in each patient. Only 60 per cent. showed leucocytosis varying from a slight to a marked degree. The erythrocyte count showed anaemia with counts varying from 1 to 3.9 million in 31.7 per cent of the cases. The haemoglobin content was low but not severely so in most instances.

Slight albuminuria occurred in 195 cases, of which 97 showed casts and 34 haematuria.

The patients were generally treated as soon as spirochaetes were found in the blood, by injections of neocarsphenamine. The average time for the disappearance of spirochaetes was 15½ hours after treatment and out of 28½ treated cases 16 required a second treatment. The dose was usually 10 mgm per kilo body weight. Finally the author

gives a list of the complications and associated conditions in these relapsing fever patients the most common being syphilis opium addiction and scabies. E H

DIGONNET (L.) & MATHIS (Maurice) Spirochétose récurrente africaine à tiques évoluant chez une femme enceinte [Tick-transmitted African Relapsing Fever developing in a Pregnant Woman.]—*Bull Soc Path Exot* 1939 Feb 8 Vol 32 No 2 pp 143-145

The description of a case of relapsing fever in a woman at Dakar infected by the bites of *Ornithodoros erraticus* during the second month of pregnancy who in spite of two relapses and various signs suggestive of abortion or premature delivery completed the gestation and gave birth to a normal infant

The patient received without any apparent inconvenience 2 10 gm of sulpharsenobenzol intramuscularly and 4 5 gm of trypanamide intravenously At birth the blood from the umbilical cord was inoculated into rats with negative results

The authors consider that the early treatment was largely responsible for the favourable course of the disease and of the pregnancy

SIMONS (H) Nouvelle méthode d'enrichissement pour certains spirochètes sanguicoles au moyen de taurocholate de bleu de méthylène [A New Method of concentrating Certain Blood Spirochaetes by Means of Taurocholate of Methylene Blue.]—*Ann Parasit Humaine et Comparée* 1939 Jan. 1 Vol 17 No 1 pp 62-68. [10 refs]

The author has developed a system first recommended by HOEFER (1919) for the diagnosis of certain protozoal infections of exposing 10 cc. or more of the blood or other material to be examined to a haemolytic system which will dissolve the blood elements but leave the parasites.

It has been generally believed that 10 per cent sodium taurocholate dissolved spirochaetes but the author finds that *S. gallinarum*, *S. duttoni*, *S. persica* and *S. turicatae* persist for several weeks in such a solution although *S. pallida* and *S. icterohaemorrhagiae* are rapidly attacked Accordingly a technique has been developed for the examination of spirochaetes in blood and other tissues employing this cytolytic agent. 2 cc. of 10 per cent sodium taurocholate dissolved in sodium citrate solution or physiological saline is mixed with 1 cc. of saturated methylene blue dissolved in saline This mixture will keep or about one month if preserved in a well corked bottle preferably in the ice chest.

For the examination of blood containing moderate numbers of spirochaetes 2 to 4 loopfuls of the taurocholate and stain are mixed on slide with an equal quantity of the infected blood. After a few seconds the drop is covered and can be examined by direct illumination when almost all traces of the blood cells will be found to have disappeared and the spirochaetes coloured blue are readily seen If very few spirochaetes are present it is possible to collect together all the material left on the slide as the organisms are entangled in a coagulum and all cellular elements disappear In this way one can

TABLE

Showing the minimum lethal concentration in vitro at 37°C of various compounds for normal and solganal-fast strains of spirochaetes and for normal trypanosomes.

Drug	Minimum lethal concentration γ per ml.						Ratio between trypanocidal and spirochaetocidal activity
	Normal spirochaetes		Resistant spirochaetes		Trypanosomes		
	Within 8 hours	Within 24 hours	Within 8 hours	Within 24 hours	Within 6 hours	Within 24 hours

LEPTOSPIROSIS

PRECIS OF ABSTRACTS IN THIS SECTION

BESSEMAN and his co-workers (p. 769) deduce from examination of urine and the results of serological tests of dogs and of a few suspicious cases of jaundice in man, that leptospiral infections are rare occurrences in Belgium. In Dalmatia, on the contrary, TARTAGLIA (p. 768) proved its presence in eleven agriculturists and fishermen and found also that in certain districts in the environs of Metkovic up to 20 per cent. of the rats examined were harbouring the organism. MONTESIRUC and his colleagues (p. 770) describe two cases in Martinique one ending fatally—these are believed to be the first recorded in the island. The succeeding four papers abstracted deal mainly with the clinical aspect. SJÖSTRÖM of Sweden (p. 770) relates three fatal cases, in one of which death took place on the eighth day of illness. Though these

three occurred in separate years the author is of opinion that the disease is not very rare in that country. DENÉCHAU and MANDROUX (p 771) mention a case with an incubation period of 17 days the patient recovered after an illness of 13 days during which he exhibited meningeal symptoms but strange to say no jaundice. The next two also describe meningeal symptoms. MURGATROYD's record (p 771) is of a very chronic case in which the leptospira was recovered from the cerebrospinal fluid up to eight months after the onset of illness. In ESCHBACH's patient (p 771) in addition to the symptoms of encephalomyelitis there was a cutaneous eruption with adenitis. [It seems to be taken for granted that all these were aetiologicaly connected with the leptospiral infection.]

CARLINFANTI (p 771) has studied the antigenic properties of *Leptospira icterohaemorrhagiae* employing alcoholic extracts of various strains and suggests that the reaction which occurs between syphilitic sera and leptospiral lipids may be due to a common alcohol-soluble partial antigen. MORROW and his fellow workers (p 772) describe the cultivation of *L. icterohaemorrhagiae* on fowl embryo chorio-allantoic membrane and PAPAGEORGIU (p 773) by serological investigations comprising the complement fixation tests employing phenolized cultures as antigen and by agglutination methods comes to the conclusion that the various strains—human canine and slime fever strains—are antigenically related. Though some sera gave agglutination but not complement fixation most yielded accordant results with both tests. H H S

BESSEMANS (A) WITTEBOLLE (P) & DE BORCHGRAVE (O) *Leptospiroses canicole et ictérohémmorragique en Belgique* [*Leptospira canicola* and *L. icterohaemorrhagiae* in Belgium.]—*C R Soc Biol* 1938. Vol. 129 No 32. pp 906-908 [22 refs.]

The authors examined the urine of 86 dogs from the neighbourhood of Ghent for the prevalence of leptospiral infection with uniformly negative results. The serological examination of 68 also gave negative results, except in the case of one dog which was jaundiced and whose serum produced lysis of *L. canicola* at first in dilutions of 1 500 and eight days later up to 1 5 000. Serological tests with *L. icterohaemorrhagiae* were negative.

In addition the authors examined various human sera including 3 suspected cases of jaundice 5 from Waken and 358 Wassermann sera. Of these only 2 of the latter were positive 1 lysing *L. canicola* up to 1 200 and the other *L. icterohaemorrhagiae* up to 1 500. It would seem therefore that leptospiral infections are rare in Belgium.

TARTAGLIA (Pierre) *La spirochétose ictéro-hémorragique en Dalmatie*. [*Spirochaetal Haemorrhagic Jaundice in Dalmatia.*]—*Bull Office Internat d'Hyg Publique* 1939 Mar Vol. 31 No. 3. pp 478-481

A description of 11 cases of Weil's Disease in Dalmatia all of which were diagnosed by serological tests.

Two of these cases occurred at Split and 9 in the neighbourhood of Metkovic 9 of them had showed jaundice and 2 were without it. All the patients with one exception were agriculturists and 9 of them

engaged in eel fishing in fresh water where they might be exposed to contamination. Wild rats were found to harbour the infection near Metkovic, the percentage of rats showing spirochaetes ranging from 11 to 20 per cent. The pH of the waters in that neighbourhood varied from 6.7 to 7.0 which would favour the survival of spirochaetes entering the water as a result of contamination with the urine of infected rats. E H

MONTASTRUC (E), DE PALMAS (M), PIGNON (A.) & MACALLOX GRANGEAU (E). Premiers cas de leptospiroses diagnostiqués à la Martinique. (The First Cases of Leptospirosis Diagnosed in Martinique.)—*Bull Soc Path Exot* 1939, Nov 9 Vol. 31 No 9 pp. 824-829

The description of two cases in Martinique, one fatal, presenting symptoms suggestive of Weil's disease. Leptospira were found in the urine of the first case and in liver smears from the second (fatal) case. Attempts to isolate the organism by guinea-pig inoculation and by culture methods were unsuccessful, but the clinical symptoms were characteristic. About the same time as these two cases, there were numerous cases of a disease resembling dengue and it is suggested [on very slight evidence] that these might have been mild cases of a leptospiral infection. MOONTAN (A.) & ESSEVELD (H). Over de frequentie van leptospirose in Ned Indië. (The Frequency of Leptospirosis in the Netherlands Indies.)—*Geneesk Tijdschr v Nedert Indië* 1939 Feb. 23, Vol. 79 No 9 pp. 547-563 [60 refs.]

SJÖBERG (Sven-Gösta). Malignant Cases of Weil's Disease with Special References to Early Diagnosis.—*Acta Med Scandinavica*, 1939 Vol. 88, No. 6, pp. 538-541 [14 refs.]

A history of a fatal case of Weil's disease occurring in a clerk who lived near Stockholm and suddenly developed the disease without knowledge of any exposure to infection (rats, etc.) but since he lived by a lake known to contain leptospira pathogenic to dogs, this may have been the source of infection. The early symptoms suggested influenza but jaundice developed on the 5th day, then collapse, hypotension, anuria, uremia and death on the 8th day. Hyperglycemia, a rare symptom, was also present.

Two similar fatal cases occurred in the same hospital (Seraphimer) in 1934 and 1935. The diagnosis was confirmed by blood cultures which were positive on the 5th day of the disease, by the injection of guinea-pigs with urine and the presence of spirochaetes in the liver.

The author is of the opinion that Weil's disease in Sweden is not very rare and advocates the use of blood cultures to arrive at an early diagnosis in suspected cases, since serum therapy should commence as soon as possible. E H

Further notes on a case of chronic meningitis in Weil's disease. [See this *Bulletin* 1937 Vol. 34 p 359.]

In view of the recovery of leptospira from the patient's cerebro-spinal fluid 6 and 8 months respectively after the onset of the disease, it had been suggested that the guineapigs used for the diagnostic inoculations might have suffered from extraneous infections.

This patient's serum more than two years after his attack has recently been examined by Major H. C. Brown, and found to agglutinate leptospira to a titre of almost 1 in 1000. These results confirm the original diagnosis and show that this patient had acquired a leptospiral infection which remained active for more than eight months. E H

The author tested the properties of alcoholic extracts of various strains of *Leptospira*, including two Weil strains 'Chinese' and rat 104 one dog strain 803/04 and a strain 'Moscow' of *S. grippotyphosa*.

The extracts were prepared by growing each strain in 5 litres of 10 per cent rabbit serum with 90 per cent. tap water and after passing through filter paper centrifuging the well grown cultures for an hour

Ten volumes of 96 per cent. alcohol were then added to the sediment and the mixture left in the incubator shaken from time to time and finally filtered. The filtrate containing the extract was diluted with 10 to 15 volumes of normal saline before being used.

Rabbits inoculated with strains of living or dead leptospira developed immune sera which gave specific complement fixation with these alcoholic extracts and also positive flocculation tests. These reactions occurred not only between extracts of any particular strain and its homologous antiserum, but also between extracts of heterologous strains and various leptospiral antisera. However leptospiral antisera gave completely negative reactions with Wassermann antigens. It would seem that the antisera react only with leptospiral lipoids and not against a ubiquitous lipoid, as in the case of *S. pallidus*.

The serum of patients with Weil's disease and of dogs infected with Stuttgart disease was found to react with leptospiral extracts but not infrequently positive results were also obtained with alcoholic organ extracts. The serum of mice infected with relapsing fever and of rabbits immunized against various bacteria, gave no reaction with leptospiral extracts. Positive Wassermann sera of syphilitic patients gave negative reactions when the leptospiral extracts were used as antigen, but gave positive flocculation tests.

It seems not unlikely that this reaction between syphilitic sera and leptospiral lipoids depends on the presence in both the leptospira and Wassermann antigen of a common alcohol-soluble partial antigen.

These results are of especial interest as they show the application to other infections of Hirschfeld and Klinger's flocculation test for the serum diagnosis of syphilis.

MORROW (Grant) SYVERTON (Jerome T) STILES (William W) & BERRY (George Packer) The Growth of *Leptospira icterohemorrhagiae* on the Chorio-Allantoic Membrane of the Chick Embryo—*Science* 1938 Oct. 21 Vol. 88, No 2238, pp 384-385

The authors have succeeded in growing a human strain of *Le. icterohemorrhagiae* on the chorio-allantoic membrane of the fowl embryo.

Eggs that had been incubated for ten days were each inoculated on the chorio-allantoic membrane with 0.1 cc. of a positive culture. Transfers were made every four or five days by grinding up two or three membranes in Locke's medium to make a 10 per cent suspension and inoculating 0.1 cc. The spirochaetes were carried through twenty successive passages in developing eggs and every five passages guinea pigs injected with the "transfer inoculum." In every case these animals became infected and died in six to eight days with typical symptoms of Weil's disease.

The organisms were found to invade the tissues of the developing embryo and produced death within six to seven days. Grossly the membranes showed grayish opaque pin-point nodules, the result mainly of localized proliferation of the ectoderm cells, and of oedema, proliferation of the fibro-blasts and infiltration of a few inflammatory cells in the mesoderm. Sections stained by Levaditi's silver method showed the presence of spirochaetes both in the membranes and embryos.

PAPAGEORGIU (S) Ueber die Komplementbindungsreaktion bei Leptospirosen [The Complement Fixation Test for Leptospira].—*Ztschr f Immunitätsf u Experim Therap* 1938. Dec 12. Vol 94 No 5/6 pp 489-504 [37 refs.]

The author has made a comparative study of the complement fixation test and agglutination reactions of 31 sera from various cases of typical Weil's disease also of dog and slime-fever strains and in addition of monovalent immune sera against ten various leptospiral strains

As antigen for the complement fixation tests well-grown cultures were killed by the addition of 0.3 per cent. phenol and after passing through filter paper centrifuged for at least four hours at 3 000-3,500 revolutions.

The results of the tests show that in a large number of sera similar results are obtained with both the complement fixation test and agglutination. In some cases however a serum would give a positive agglutination reaction whilst the complement fixation test was negative. Whilst the agglutination showed a constant strain or group specificity the complement fixation test seemed to have a greater range in its reaction.

The results confirm the generally accepted view that antigenically the different strains of leptospira are all more or less related.

RAT-BITE FEVER.

PRÉCIS OF ABSTRACTS IN THIS SECTION

COLARUSSO (p 773) records two cases both diagnosed on the grounds of history and symptoms, for the spirillum was not seen in the blood of either patient. One was a boy of 14 the other a man of 52 years both were bitten on the finger and in both cases symptoms set in after the wound had apparently healed completely. In YAMAMOTO's contribution (p 774) and in the succeeding article are recorded cases of sodoku following bites by cats. Two of the three were typical in course the third developed a complicating periorchitis and epididymitis. MOLLARET and BONNEFOI (p 774) discuss the rôle of the cat in transmission of sodoku and point out that further investigation is needed to decide whether the cat is a true reservoir of the spirillum or whether it acts as an incidental transmitter from an infected rat which it has killed or eaten.

H H S

COLARUSSO (Andrea) Su due casi di sodoku. [Two Cases of Rat-Bite Fever].—*Riforma Med* 1938 Dec. 3 Vol. 54 No 43 pp 1839-40 1843-4 1845-6 [26 refs.]

The first patient was a lad of 14 years bitten on the finger by a field rat which he was trying to capture. The wound healed without treatment. Four weeks later he felt local pain and had a rigor with typical fever course and enlargement of regional glands. The second was a man of 52 years also bitten on the finger and in his case too the

Ten volumes of 96 per cent. alcohol were then added to the sediment and the mixture left in the incubator shaken from time to time and finally filtered. The filtrate containing the extract was diluted with 10 to 15 volumes of normal saline before being used.

Rabbits inoculated with strains of living or dead leptospira developed immune sera which gave specific complement fixation with these alcoholic extracts and also positive flocculation tests. These reactions occurred not only between extracts of any particular strain and its homologous antiserum, but also between extracts of heterologous strains and various leptospiral antisera. However leptospiral antisera gave completely negative reactions with Wassermann antigens. It would seem that the antisera react only with leptospiral lipoids and not against a ubiquitous lipoid, as in the case of *S. pallida*.

The serum of patients with Weil's disease and of dogs infected with Stuttgart disease was found to react with leptospiral extracts, but not infrequently positive results were also obtained with alcoholic organ extracts. The serum of mice infected with relapsing fever and of rabbits immunized against various bacteria, gave no reaction with leptospiral extracts. Positive Wassermann sera of syphilitic patients gave negative reactions when the leptospiral extracts were used as antigen, but gave positive flocculation tests.

It seems not unlikely that this reaction between syphilitic sera and leptospiral lipoids depends on the presence in both the leptospira and Wassermann antigen of a common alcohol-soluble partial antigen.

These results are of especial interest as they show the application to other infections of Hirschfeld and Klinger's flocculation test for the serum diagnosis of syphilis.

MORROW (Grant) SYVERTON (Jerome T.) STILES (William W.) & BERRY (George Packer). The Growth of *Leptospira icterohemorrhagiae* on the Chorio-Allantoic Membrane of the Chick Embryo.—*Science* 1938 Oct. 21 Vol 89, No. 2286, pp 384-385.

The authors have succeeded in growing a human strain of *Leptospira icterohemorrhagiae* on the chorio-allantoic membrane of the fowl embryo.

Eggs that had been incubated for ten days were each inoculated on the chorio-allantoic membrane with 0.1 cc. of a positive culture. Transfers were made every four or five days by grinding up two or three membranes in Locke's medium to make a 10 per cent. suspension and inoculating 0.1 cc. The spirochaetes were carried through twenty successive passages in developing eggs and every five passages guinea pigs injected with the "transfer inoculum." In every case these animals became infected and died in six to eight days with typical symptoms of Weil's disease.

The organisms were found to invade the tissues of the developing embryo and produced death within six to seven days. Grossly the membranes showed grayish opaque pin-point nodules, the result mainly of localized proliferation of the ectoderm cells, and of oedema, proliferation of the fibro-blasts and infiltration of a few inflammatory cells in the mesoderm. Sections stained by Levaditi's silver method showed the presence of spirochaetes both in the membranes and embryo.

Malaria is only feebly endemic in Coquilhatville in the Congo SCHWETZ and BAUMANN (p 777) found low infection rates at all ages but higher in adults than children *A. marshalli* var *moucheti* a potential vector is common, but *A. gambiae* was not seen *P. vivax* was not found The films were taken at the most unhealthy time of the year In a further investigation in the lower reaches of the Congo River basin however SCHWETZ and GERONVEZ (p 777) found low rates in Thysville 800 metres above sea level and well away from the river very high rates at Luozi on the river bank and moderate rates at Timanzi 750 metres above sea level and away from the river *P. vivax* was common at Luozi but rare in the other two places The examinations were made at the end of the dry season In the Kwango River area the same authors (p 778) found high parasite rates in children with many gametocytes though parasites were not numerous In the river-side places *A. gambiae* was very prevalent *P. vivax* was rare and *P. falciparum* and *P. malariae* were about equally prevalent These examinations were made in the dry season

In Holland according to VAN THIEL and BEVERE (p 778) *A. maculipennis atroparvus* prefers pig to man in the proportion of 12 to 1 and in Italy *labranchiae* and *clutus* appear to prefer man though the results were not so marked In Hanoi CHEDECAL (p 779) observed that horses proved attractive to *A. vagus* and *A. hyrcanus* var *sinensis* which though common in stables were rarely found in adjacent houses This fact is of value in prophylaxis VARGAS (p 779) in Timuxco found that 33 per cent. of 420 *A. pseudopunctipennis* preferred to feed on man when given an equal opportunity of feeding on animals

In the *Bulletin de l'Office Internationale d'Hygiène Publique* it is shown that in Egypt *A. pharoensis* is a common vector and *A. sergenti* a probable vector In the Congo DUREN (p 780) found that the species carrying malaria are *A. gambiae* *A. funestus* *A. moucheti* *A. nili* *A. pharoensis* and *A. rufipes* but the last two are so rare that their rôle in this respect is negligible

BOYD and MATTHEWS (p 780) investigated two patients 7 years after infection with the McCoy strain of *P. vivax* Immunity was clearly present although no parasites were found in their blood when tested by injection into other patients Reinfection with heavy doses of the same strain produced only slight parasitological responses and a slight clinical attack in one patient only The antigenic identity of the parasite has therefore been maintained through 40 passages in man and anophelines.

In endemic areas SICAUT and MESSERLIN (p 781) observed that although spleen and parasite rates decreased with age the serological index increased Of the inhabitants 44 per cent showed neither parasites, enlarged spleen nor positive melanoflocculation and were no more prone to febrile attacks than those showing evidence of infection The authors therefore consider that a true immunity not depending upon the existence of parasites in the body may develop side by side with premunition DECOURT (p 782) states his experience that the value of Henry's reaction has been established but that a positive result does not always indicate parasites in the blood The intensity of the reaction in naturally acquired malaria varies directly with the number of attacks He postulates a non-specific as well as a specific immunity but Henry's reaction cannot distinguish between them.

JOLLY and DANGLEMONT (p 782) from a study of two cases of pernicious *P. falciparum* malaria note an early marked increase of

the blood urea. Heavy infections with all stages of schizontic forms were present and owing to the rapid destruction of parasites and red cells the phagocytes were unable to deal with the debris. Mobilization of phagocytes may contribute to capillary embolism and blocking of the kidneys and the resulting coma is both parasitic and toxic. Prognosis depends on attempts to restore renal function.

SCHWETZ (p. 783) discusses congenital malaria, considering it to be an incident in acute malaria of the mother. In populations suffering from endemic afebrile malaria the results of investigations of congenital malaria are consistently negative.

GARDNER and DEXTER (p. 783) report a patient infected by *P. malariae* after a blood transfusion from a donor who had not had an attack of malaria for 17 years, during which time he had lived in northern U.S.A. No parasites could be found in the blood of this donor. Successful treatment with sulphathiazide is recorded.

TECHILON (p. 784) reports a case of what he regards as paramalarial hepato-splenomegaly with infantilism. ROGER and BOUDOUVERGUES (p. 784) have seen only one case, in 15 years, in which they were satisfied that polyneuritis was caused by malaria. Many malarial patients attend their clinic.

PRI DIBBOSE (p. 784) gives a method for the detection and estimation of quinine in urine, blood or vacera. For details the original abstract should be consulted.

In treatment MALYCKEVA (p. 785) obtained rather better ultimate results by spreading the administration of atequine (atebrin) over 11 days in a period of one month than as a 7 consecutive days course. TERCHLER (p. 785) considers that short courses of atequine 0.1 gm. three daily for 3 days, can maintain the health of a native labour force in highly malarial districts of Tanganyika Territory. CROPPA and BASO (p. 786) report that treatment of 3 gametocyte carriers of *P. falciparum* with cibonal and atequine for 5 days did not prevent infection of 4 *stephensi* from them.

The results of the treatment of benign and malignant tertian malaria with prontosil rubrum and prontosil soluble obtained by MINA and MOHR (p. 786) were unsatisfactory. The state of immunity is probably a factor in this treatment. But FARRAUX and RAGNOT (p. 786) report that the schizonticidal action of solaseptazine justifies its use.

VAN RIEL (p. 787) found that cuprochin was ineffective in *P. falciparum* malaria.

Acute treatment was successful in the hands of SERRA (p. 787).

In discussing the relationship between irrigation and malaria in India RISSALL (p. 787) points out that it is defective irrigation which is responsible. Many items are detailed but perhaps the most important are the absence of drainage canals and general untidiness through neglect of proper maintenance and planning of the canals and channels. Sub-sol water has in places risen greatly through the effects of barrage construction. He urges organization and co-operation between all agencies concerned, but his detailed recommendations are to be published later.

AFANASSIEV (p. 788) has tested and recommends the distillate of coke filters obtained in the final stages of fractional distillation of Russian petroleum for the destruction of anopheline larvae in nature, using doses generally employed with petroleum.

ROY (p 789) does not consider that the small fish *Panchax panchax* common in Bengal is of much value in anti larval work. C W

WATSON (Malcolm) *Malaria and Mosquitoes Forty Years On.*—Paper read before the Dominions and Colonies Section of the Royal Society of Arts on Feb 7 1939 [Uncorrected proof.]

This is an interesting narrative of the progress in the prevention of malaria since Ross made his discovery in 1898. Ross's hopes and disappointments early failures in attempts at anopheline control and their effect in retarding malaria prevention successes in Panama and Malaya species sanitation recent progress in many parts of the world and the contribution to malaria control made by the Ross Institute are graphically described. Norman White

SCHWETZ (J) & BAUMANN (H) *Recherches sur le paludisme endémique chez les noirs de l'agglomération de Coquilhatville* [Endemic Malaria among Native Inhabitants of Coquilhatville]—*Ann Soc Belge de Méd Trop* 1938 June 30 Vol 18 No 2 pp 259-276

A very careful parasite survey revealed the surprising fact that malaria in Coquilhatville is very feebly endemic. Coquilhatville is situated on the Equator at the junction of Ruki River with the Congo. The climate is therefore hot and moist and the seasons are little marked. The blood films were taken at the most unhealthy time of the year. An insignificant number of infants below the age of two years was found infected the proportion of infected among children from 3 to 5 was slightly higher but here again the number of parasites harboured by the infected was very small. Between ages 5 to 10 the proportion infected was about the same as for the 3-5 age group but the parasites were somewhat less numerous. Thereafter there was a progressive diminution of the numbers infected and the parasites harboured till adult age. Low as was the degree of infection of adults it was higher than that of infants a very exceptional finding in the Congo. Gametocyte carriers were very rare. *P. vivax* was not found at all and *P. malariae* was extremely rare. Mosquitoes are very numerous. The most common anopheline in Coquilhatville was *A. marshalli* var *moucheti* a potential vector. *A. gambiae* almost ubiquitous in the Congo was not noted. Further observations will be awaited with interest.

N W

SCHWETZ (J) & GERONNEZ (E.) *Sur le paludisme endémique du Bas-Congo IV—Le paludisme chez les noirs de la région des Cataractes.* [Endemic Malaria among Inhabitants of the Cataract Region of the Lower Congo.]—*Ann Soc. Bdge de Méd Trop* 1938. June 30 Vol 18 No 2. pp 277-282.

This note records the results of the examination of 275 natives, mostly children in September-October the end of the dry season in three places in the Cataract Region between Leopoldville and Matadi. Thysville about 800 metres high, is on the Leopoldville Matadi railway line. Luiza is on the bank of the river Timanzi between the river and the railway is about 750 metres high on a plateau. In Thysville the proportion of infected was low and in them parasites were few. *P. vivax* was very rare. In Luiza the infection rate was very

high, parasites were very numerous and double or triple infections were common, as were gametocyte carriers. *P. vivax* was much in evidence. The spleen rate of the 71 children examined was 78.9 per cent. and the parasite rate 85.8 per cent. In Tumana there was a spleen rate of 40 per cent. and a parasite rate of 82 per cent. (73 children examined). Parasites were relatively few in numbers, mostly discoverable only in thick drops. Very few cases of *P. vivax* infection were noted. The different degrees of endemicity in three adjacent places is noteworthy.

V IV

SCHWETZ (J) & GEROSVEX (E.) Sur le paludisme endémique du Bas-Congo. I.—Le paludisme chez les noirs de quelques agglomérations riveraines du Kwango. [Endemic Malaria among Natives in Certain Villages on the River Kwango, Lower Congo].—Ann. Soc. Belg. de Méd. Trop. 1938. June 30. Vol. 18. No. 2. pp. 283-289.

A note on the findings in blood films of 296 natives living between Popokabaka and the Wilham Falls gives an indication of the degree of endemicity of malaria in the Kwango region. The films were taken in the dry season. Everywhere *A. gambiae* was the prominent vector. In Popokabaka 23 out of 24 infants between 9 months and 2 years harboured parasites. 23 out of 23 children from 2 to 5 years. 16 out of 23 children from 6 to 14 and 6 out of 19 adult women. Parasites were relatively few in number. *P. malariae* was very frequently found. *P. vivax* was seen in only 3 cases. A large proportion of infants below 5 years harboured gametocytes. In Kasongo Linda 23 infants up to 5 years of age were all infected as were 28 out of 30 children from 6 to 14 years. Twenty out of 42 adult women harboured parasites. Here again parasites were few in number. In children from 2½ to 5 years more than half the parasites were *P. malariae*. *P. vivax* was seen only once. In Mahonga on the Kasanga plateau, where no anophelines were found, only 1 of 9 infants below 2 years was infected. 10 of 12 children from 3 to 5. 7 of 22 from 5 to 14 and 10 of 96 adults. Parasites were few in number. In Holomoni near the Francis Joseph Falls 8 of 7 children below 4 years were infected. Above that age only 1 of 16 examined harboured parasites. All the places mentioned except Mahonga are situated on the Kwango River. In these river-side places *A. gambiae* is very prevalent. Though the percentage infected was high parasites were few. *P. falciparum* and *P. malariae* were almost equally prevalent, *P. vivax* very rare. The proportion of *P. malariae* infections on the Kwango River is unusually high.

V IV

van THIEL (P) & BEVERE (L.) Preuve expérimentale de l'anthrophilie d'*Anopheles maculipennis labranchiae* et *clutus*. [Experimental Proof that *Anopheles maculipennis labranchiae* and *clutus* prefer Human Blood.].—Bull. Soc. Path. Exot. 1939. Jan. 11. Vol. 32. No. 1. pp. 103-109.

The authors have offered man and pig to *Anopheles* which were confined in a very large cage under conditions which approached the natural.

The experiments were carried out in a large cage of mosquito netting, measuring about 18 x 23 ft. x 7 ft high. In this a man and a pig spent

the night in small chambers mosquitoes liberated in the main cage could enter either small chamber but could not escape from it. The apparatus appears to be simpler and therefore better than that previously described by REUTER [see this *Bulletin* 1937 Vol 34 p 630]. Working in Holland the authors found that the local *aloparvus* prefer pig to man the numbers attacking the two hosts differing on the average of 12 to 1. The apparatus was then moved to the province of Foggia Italy and tested with *labranchiae* and *clutus* which were caught in stables kept for one to three days and then liberated in the large cage. A number of difficulties were encountered and the figures which are given at length are not perhaps quite conclusive though perhaps statistical tests appropriate to small numbers would be helpful. Generally speaking it seems that man was bitten by about twice as many of these mosquitoes as pig.

CHEDECAL. Contribution à l'étude du comportement trophique des anophélines à Hanoi. (Enclos du 9e R.I.C.) Feeding Characteristics of Anophelines in Hanoi.—*Rev Méd Française d'Extrême-Orient* 1938 Oct Vol 21 No 8. pp 1007-1011.

Urbanization has much diminished the prevalence of anophelines in Hanoi but there are areas where they are still to be found. Among these is the citadel in which the 9th R.I.C. are stationed. The lines contain stables which accommodate 160 horses. Anopheles found were *ragus hyrcanus* var *sinensis tessellatus* and *aconitus*. *A. ragus* and *A. sinensis* were much the most prevalent. There was no locally contracted malaria during the seventeen months of the observations the 84 cases that did occur among the garrison of 900 were all old infections. No case of malaria occurred among the officers children housed nearby. Anophelines were very rarely found in human habitations but they were always present in large numbers in the stables. Of engorged anophelines only 0.9 per cent. of *sinensis* contained human blood and only 2.7 per cent. of *ragus*. Nearly all the others contained horse blood. The attraction of horses for anophelines is thus marked and is of value in prophylaxis.

A W

VARGAS (Luis). Observaciones sobre la preferencia alimenticia sanguinea de la *Pseudopunctipennis* en Temixco Morelos. [Blood Preferences of *A. pseudopunctipennis* in Temixco.]—*An Inst Biol Mexico*. 1938 Mar & June Vol 9 Nos 1 & 2. pp 201-208.

In Temixco which is highly malarious, *A. pseudopunctipennis* is the sole vector. Of 245 engorged females of this species captured in houses 67.6 per cent. contained human blood. By the use of mosquito traps such as those described by EARLE & HOWARD as used in Porto Rico [this *Bulletin* 1937 Vol 34 p 636] *A. pseudopunctipennis* was given equal opportunities of feeding on man or one or other of several of the lower animals. Of 420 mosquitoes with equal facilities of feeding on man or cow 33 per cent. fed on man. Of 677 mosquitoes with a horse as an alternative food supply to man 27 per cent. selected man.

N IV

BULLETIN DE L'OFFICE INTERNATIONAL D'HYGIÈNE PUBLIQUE. 1938. Dec. Vol. 30. No. 12. pp. 2789-2792.—La transmission du paludisme par les diverses espèces d'anophèles égyptiens. [Transmission of Malaria by Egyptian Species of Anopheles.]

The most prevalent species of *Anopheles* in Egypt are *pharoensis multicolor mauritanicus* and *sergenti*. Other species found with a local distribution, and playing no part in the spread of malaria in the Nile valley, are *rhodensis (dihali)*, *superficulus aegypti* and *turkhardi*. *A. pharoensis* is readily infected in the laboratory and has been found infected in nature. It is commonly found in human habitations. It explains the relation between rice cultivation and malaria prevalence: rice fields are favoured breeding places. It is the most prevalent anopheline in Egypt. *A. multicolor* has never been found infected and it is very rarely found in human habitations though these be close to breeding places of this species. *A. sergenti* has been found harbouring oöcysts but not sporozoites. It is easily infected experimentally. It is very probably a vector. *A. mauritanicus* enters habitations and bites man but it has not been found naturally infected: an attempt to infect it experimentally failed. A 17

DUKES (A.) Etat actuel de nos connaissances sur les anophèles du Congo belge. [Present Knowledge of Anopheles of Belgian Congo.]—Ann Soc Belg de Méd. Trop. 1938 Dec. 31 Vol. 18. No. 4 pp. 557-580. With 5 maps. [13 refs.]

The author has gathered together all available information concerning the species of Anopheles that have been found hitherto in the Belgian Congo. Maps illustrate the distribution of the most prevalent species. Following the recent classification of EDWARDS and EVANS the list of Anopheles contains 32 species and 6 varieties. The only species that have been incriminated as vectors of malaria are *gambiae fuscipes*, *mosaici*, *nilis pharoensis* and *rufipes*. The two last named are so rare that their importance as transmitters is negligible. It is not possible to summarize in small space the large amount of information that this paper contains. N 17

BOYD (Mark F.) & MATTHEWS (Chance B.) Further Observations on the Duration of Immunity to the Homologous Strain of *Plasmodium vivax*.—Amer J Trop Med. 1939 Jan. Vol. 19 No. 1 pp. 63-67.

The first-named author reported in 1936 that an effective homologous immunity to the McCoy strain of *Plasmodium vivax* may endure for

more than three years. The conclusion was based on observations made on a patient who was re-examined from the same point of view in 1938 nearly seven years after the primary attack. Observations are also reported on another patient whose primary attack was almost contemporaneous with that of the first.

The first patient was first inoculated with the McCoy strain in December 1931 a primary attack lasting 22 days was followed by two relapses. Three and a half years later he was inoculated intravenously with 18 cc. of blood containing 180 million trophozoites of the same strain. There was no clinical reaction. In July 1938 he harboured no detectable parasites and inoculation of 10 cc. of his blood into a susceptible patient showed that he had no submicroscopic latent infection. He was then bitten by 10 infected mosquitoes nine days later parasites were detected and remained intermittently detectable for 15 days, though never more than 15 per cmm. There was no clinical reaction. The following month he was given an intravenous injection of 10 cc of infected blood containing 159 million trophozoites. There was no clinical or parasitological response whatsoever.

The second patient whose primary attack was in August 1931 was also shown to have no latent malaria infection in July 1938. He was bitten by 8 demonstrably infected mosquitoes nine days later parasites were detected and he experienced a clinical attack consisting of but one paroxysm. Parasites were detectable for 10 days the maximum density being 1100 per cmm. After the disappearance of the parasites he too received an intravenous injection of the same amount of infected blood and from the same source as the first patient received. Eight days later parasites were detected for three days but never exceeding 20 per cmm. There was no clinical reaction.

The observations show that during the period of more than six years the McCoy strain of *P. vivax* has maintained its original antigenic identity through 40 human-anopheline passages. A II

SICAULT (G.) & MESSERLEY (A.) *Index sérologique et prémunition dans le paludisme endémique* [Serological Index and Premunition in Endemic Malaria.]—*Bull. Soc. Path. Exot.* 1938. Dec. 14 Vol. 31 No 10 pp 911-915

The serological technique used in this inquiry was the authors micro-reaction [see this *Bulletin* 1939 Vol. 36 p 395]. In endemic areas the spleen, parasite and serological indexes were determined for persons in age groups as follows:—0-5 years, 127; 6-10 years, 105; 11-16 years, 69; adults, 498. The spleen index (44.9, 45.7, 52.1 and 25.8) and the parasite index (44.3, 31.4, 30.4 and 19.6) decrease as age advances; the serological index increases (25.9, 33.3, 39.1 and 52.4). During attacks of fever melano-flocculation is often negative. Nearly all patients with very large spleens in the absence of fever gave positive melano-flocculations. Among the inhabitants of an endemic area in relatively good health 44 per cent. showed neither parasites nor enlarged spleen nor a positive serological reaction. Six months observation showed that this portion of the population was not more prone to febrile attacks than those with some positive sign of malaria infection. The authors conclude that in endemic malaria side by side with premunition which is dependant upon the existence of parasites in the body a true immunity not dependant upon the existence of parasites may be developed. A IV

DECOURT (Ph.) Sérologie et Immunité au cours du paludisme. A propos de la communication de G. Sicault et A. Messerlin. [Serology and Immunity in Malaria with reference to the Work of Sicault and Messerlin.]—*Bull Soc Path Exot.* 1939 Jan. 11 Vol. 32. No. 1 pp 7-11

The author refers to a report by SICAULT and MESSERLIN on the determination of a serological index in a region of high malaria endemicity and to their discussion of malaria immunity [see above]. He contrasts their contentions with his own findings. Ten years observations of Henry's reaction in patients undergoing malaria therapy in Paris have confirmed the value of the reaction but a positive reaction does not always indicate the presence of parasites in the blood. In patients inoculated by injection of infected blood the reaction becomes positive after a certain number of febrile attacks a positive reaction may persist after the cure of the patient, involving the eradication of the parasite, for a period longer than the duration of the malaria infection. Patients infected by injection of infected blood in non-malarial regions never relapse. In naturally acquired malaria the intensity of the reaction varies directly with the number of attacks of malaria from which the patient has suffered. In addition to a specific immunity the author postulates a non-specific immunity connected with endothelial irritation by destruction products of parasites and red-cells, especially melanin and not dependant upon the presence of the parasite. To distinguish malaria immunity from the conception of premunition which is considered too narrow the term immunition is used a term which NICOLLE employed to describe "immunity following a natural infection. Serological reactions afford evidence of immunition and may measure it to a certain degree. The author is unable to agree, however that serological reactions are either strictly specific or capable of the aetiological separation of immunological phenomena which are probably multiple and certainly very complex. JOLLA (A) & DAXGLEMONT (F) Accès pernicieux palustres à *Plasmodium falciparum* avec évolution schizogonique complète du parasite dans le sang périphérique et hyperazotémie considérable transitoire [Pernicious Attacks of *falciparum* Malaria with Complete Schizogony Cycle of Development of Parasite in Peripheral Blood and Considerable Transitory Increase of Nitrogen Content of Blood.]—*Bull Soc Path. Exot.* 1939 Jan. 11 Vol. 32. No. 1 pp 50-58. With 3 figs.

This is an interesting report of two cases of pernicious *falciparum* malaria in Guadeloupe one of which was fatal. Both were extremely heavy infections in both all stages of the schizogonic cycle of development were found in the peripheral blood rosettes were numerous. The urea content of the blood was very markedly increased quite early in the attack. When the lack of organic resistance allows this development of schizogonic forms and extremely rapid multiplication of parasites the pernicious syndrome commonly results. The schizogonic forms of *P. falciparum* are extremely fragile there is an important destruction of parasites and red cells numerous rosette forms are seen free from their red cells or phagocytosed by macrophages blood cell and parasite debris is present in such abundance that the phagocytes though increased in number are unable to cope with it.

This abundance of debris is believed by the authors to play an important part in determining pernicious attacks by mobilizing macrophages which contribute to capillary embolism and by blocking the kidneys. This blocking of the kidneys results in anuria and uraemic symptoms. The resulting coma is both parasitic and toxic. The prognosis is dependant on the result of attempts to restore renal function

SCHWETZ (J) *Considérations sur le paludisme congénital. [Congenital Malaria.]—Bull Soc Path Exot* 1939 Jan. 11 Vol. 32 No 1 pp 44-50

The author contributes no fresh observations on congenital malaria he refers to his own published findings and to numerous other reports that have appeared in malaria literature. He concludes that the numerous undoubted cases of congenital malaria reported were incidents in acute malaria that is to say that the mother had suffered from febrile attacks during pregnancy or actually during or little before confinement in nearly all these cases *P. vivax* was responsible for the infection. On the other hand the investigation of congenital malaria among populations suffering from endemic afebrile malaria has consistently given negative results and this in spite of the fact that numerous *P. falciparum* parasites were sometimes found in the maternal blood and also in the placenta. The explanation of this difference is unknown perhaps it is due to the greater friability and permeability of the placenta caused by febrile malaria. The harmful effect on the infant of malaria parasites in the placenta, reported by BLACKLOCK and GORDON 1925 has not been noted by other authors [see this *Bulletin* 1928 Vol. 23 p 130]

GARDNER (William A) & DEXTER (Lewis) *A Case of Quartan Malaria following Transfusion and treated with Sulfanilamide—Jl Amer Med Assoc.* 1938 Dec. 31 Vol. 111 No 27 pp 2473-2475 [13 refs.]

A woman aged 30 who had never had malaria nor lived in a malarious locality was operated on a cold abscess was excised. To combat post-operative weakness she was given two transfusions of 600 cc of whole blood. A month after the first transfusion she had the first of a series of severe rigors the temperature rising to 103° to 105°F. The chills occurred at regular intervals of three days. She was re-admitted to hospital ring forms and gametocytes of *P. malariae* were found in the blood. The donor of the first transfusion had had quartan malaria seventeen years previously while serving with the Italian Army in Albania. He then returned to the U.S.A. since when he has made trips to Washington and Baltimore but never farther south. He has had no attacks of fever during these seventeen years no parasites were found in his blood. In spite of this the authors believe that the transfusion was responsible for the malaria infection. There was no other possible ascertainable source of infection.

The patient was treated with sulphanilamide 3.6 gm. a day for 17 days. No toxic symptoms were observed. Chills ceased parasites disappeared and the spleen decreased in size. The authors consider that the drug should be further tried in a large series of cases of malaria

N W

TSCHILOW (Konstantin) Malarischer Infantismus. [Malarial Infantismus.]—*Wien Klin Woch.* 1939 Feb. 24 Vol. 52 No. 8. pp. 183-185

A case of a 20 year old girl with a small thyroid, appearances of myxoedema, defective mentality undeveloped genitals, complete absence of secondary sexual characters considerable enlargement of liver and spleen with intermittent haemolytic crises. After 8 months of observation and treatment with quinine and hormones menstruation developed for the first time, as well as secondary sexual characters there was also a considerable increase in weight and height. The author considers that it can be confidently asserted that this case was one of paramalarial hepato-splenomegaly although he found no malarial parasites in the blood yet the fact that the patient came from a well known malarial district and gave a history of a past malarial infection, as well as the blood picture supported the diagnosis of malaria. Further under quinine treatment the size of the liver and spleen diminished.

ROGER (Henri) & BODDORRESQUES (Jacques) La polyneurite paléoténne. [Malarial Polyneuritis.]—*Marseille Méd* 1939 Nov 5-15 Vol. 75. No 31-32 pp 493-522. [54 refs.]

A lengthy and very complete dissertation on the association of malaria with polyneuritis and a critical discussion of very numerous cases reported in the literature of the subject. That genuine malarial polyneuritis is a rare condition is shown by the fact that among the very numerous patients from malarial countries that have been seen in the Neurological Clinic of Marseilles during 15 years only one case of polyneuritis was observed in which the authors were satisfied as to the aetiological rôle of malaria. This case is described at length.

PRUDHOMME (R. O) Nouvelle méthode de dosage de la quinine. [New Method for the Detection and Estimation of Quinine.]—*Bull Soc Path Exot* 1938. Dec 14 Vol. 31 No. 10. pp 829-832

The test is based on the property possessed by quinine and several other alkaloids of forming with certain acid dyes such as eosin, coloured combinations insoluble in water but soluble in chloroform. The pH of the medium in which the reaction is determined is of great importance. The colouration of the chloroform is at its maximum between pH 6.5 and 7.8. At a given pH the tint of the chloroform is proportional to the amount of quinine present. Standard colorimetric preparations are made with varying quantities of quinine sulphate quantities which would vary according as to whether urine, blood or organs were to be examined. The author describes the technique for the examination of the urine. It is necessary to clarify the urine for which purpose a reagent must be used that does not precipitate the quinine. The author uses a 10 per cent. solution of neutral acetate of lead. The excess of lead is eliminated by the addition of sulphuric acid.

In a test tube place 10 cc. of the urine add 5 cc. of the acetate of lead solution filter to 12 cc. of the filtrate add 5 drops of sulphuric acid in a concentration of 65°B * shake and filter several times through the same paper until a perfectly clear liquid is obtained to 9 cc of the liquid add a drop of litmus solution neutralize with caustic soda 36°B * till a lilac colour is obtained 2 cc. of a phosphate solution brings the pH to 7 four drops of an eosin solution are added the tube is shaken and 3 cc of chloroform are introduced the tube is once more vigorously shaken The colour of the chloroform is compared with that in the standard tubes, containing known quantities of quinine which are prepared in exactly similar manner

MALACHEVA (A N) Evaluation comparée de l'efficacité des deux méthodes de traitement de cas aigus de tierce bénigne dans les conditions du nord. [Comparison of Two Methods of treating Acute Cases of Benign Tertian Malaria in the North]—*Med Parasit & Parasitic Dis* Moscow 1938, Vol. 7 No 5 [In Russian pp 646-653 French summary pp 653-654]

Both methods of treatment involved the use of acridine In the first method 0.15 gm twice a day was given for 7 days in the second the same doses were given for 5 days then 10 days interval then the same medication for 3 days followed by a second interval of 10 days, after which the 3 days treatment was repeated—11 days treatment in all spread over a month There were 168 patients treated by the first method 141 by the second Two-thirds of the cases were infections of the previous year that is cases of prolonged incubation or of relapses. The frequency of early relapses in the two groups was almost identical 33.6 and 35.5 per cent but the interval between the initial attack and the early relapse was greater in patients who had been submitted to the longer course Repeated relapses were hardly ever experienced in the prolonged treatment group (only 2 cases) whereas in the 7-day treatment group 13 had 2, and 4 had 3 relapses.

TEICHLER (Günther) Ueber Atebrinkurzbehandlung bei schwarzen Pflanzungsarbeitern [Short Course of Atebrin Treatment for Plantation Coolies.]—*Arch f Schiffs- u Trop Hyg* 1939 Mar Vol. 43 No 3 pp. 125-127

The observations were made on a large sisal plantation in the interior from Tanga East Africa. The author treated prophylactically 500 natives in this highly malarial district with atebrin on 3 days (1 tablet of 0.1 gm thrice daily) He inspected in the next week all those who had atebrin and he found that 10 complained of fever 4 of headache 1 of giddiness and 1 of weakness, so there was a very small percentage reporting sick He considers that by giving such short courses of atebrin he can maintain the health of the labour force working in highly malarial districts It is not to be regarded as a means of systematically eradicating malaria.

(* The terms 65°B and 36°B. refer to the Beaumé density scale. H_2SO_4 at 65°B represents 89 gm concentrated H_2SO_4 diluted with 11 gm water NaOH at 36 B. represents 30 gm solid NaOH added to 70 gm. water)

CHOPRA (R. N.) & BASU (B. C.) Studies on the Effect of Anti Malarial Drugs upon the Infectivity of Patients to Mosquitoes. Part II. "Cilonal. — *Jl Malaria Inst of India*. 1938. Dec. Vol. 1 No 4 pp 351-352.

Three *P. falciparum* gametocyte carriers were the subjects of experiment. Large numbers of *A. stephensi* were fed on them before and after treatment with cilonal. A five day treatment consisting of cilonal 0.02 gm with atebain 0.1 gm. three times a day did not prevent the development of the parasites in mosquitoes. A postscript to the paper states that two further cases were treated with cilonal 0.03 gm three times a day for five days. Crescents had not disappeared on the fourth day but the patients were not infective for *A. stephensi*.

HEMK (IV) & MOHR (IV) Zur Frage der Wirksamkeit des Prontoils bei akuter Malaria. [Activity of Prontoil in Acute Malaria.]—*Arch f Schiffsa- u. Trop Hyg* 1939 Mar Vol. 43 No 3 pp. 117-125 With 4 figs. [11 refs.]

The authors refer to the work of DIAZ DE LEÓN, VAN DER WIELEN and HILL and GOODWIN on this subject. They studied the action of prontoil rubrum and prontoil soluble in 10 cases of malaria. 3 of benign and 7 of malignant tertian infections. the former preparation is given orally and the latter by injection. The results with both drugs in the treatment of malaria were unsatisfactory and they did not confirm the more satisfactory results obtained by DIAZ DE LEÓN and GOODWIN and HILL. The explanation of the difference lay either in a difference in the malaria parasite strains or in the immunity of the patient. the authors consider the latter the most probable explanation. However the results should not interfere with further research on the action of sulphonamide bodies in malaria and possibly they might be found to have an action on the cycle of the malarial parasite in the reticulo-endothelial cells.

FARINAUD (E) & RAGIOT (Ch) Recherches sur l'emploi des dérivés de la sulfamide dans le traitement du paludisme. [Sulphamide Derivatives in the Treatment of Malaria.]—*Bull Soc Path Exot* 1938 Dec. 14 Vol 31 No 10 pp 907-910

Three malaria patients infected with *P. falciparum vivax* and *malariae* respectively were treated with intravenous injections of soluseptasine, 10 cc morning and evening for 10 days. Regular counts of parasites were made throughout the treatment. In the *falciparum* case schizonts had completely disappeared on the 6th day but gametocytes increased in number and were very numerous on the 10th day. In the *vivax* case there were 2,200 schizonts and 49 gametocytes at the beginning of treatment. the blood was clear of parasites on the 5th day. In the *malariae* case treatment appeared to diminish the number of schizonts which were however still numerous at the end of treatment. the drug had no demonstrable effect on *malariae* gametocytes. All three were mild cases. The author concludes that the schizonticidal action of soluseptasine justifies the inclusion of that drug in the list of anti malaria remedies.

VAN RIEL (J) Essai de traitement de la malaria par le cuprochin [Experimental Treatment of Malaria with Cuprochin.]—*Ann Soc Belge de Méd Trop* 1933. June 30 Vol 18 No 2 pp 339-342.

Cuprochin was formerly known as Paludex and several reports have been published concerning its value as an antimalaria remedy [this *Bulletin* 1937 Vol 34 p 596 597] now Paludex consists of one part quinine and two parts cuprochin. Cuprochin is cupro- δ -xyquinoline sodium disulphonate. The author treated 14 adults suffering from *falciparum* malaria of average severity with cuprochin. Each patient had a twenty day course of treatment one gram a day for patients weighing from 41 to 50 kgm the dose being increased for those of greater weight. Parasites persisted throughout the treatment in six cases gametocytes appeared during treatment. From the clinical point of view the drug was equally ineffective. Four children were also treated with no better results they all lost weight and the malaria persisted. N IV

SERRA (G) L'utilité de la splénocontraction dans le paludisme chronique avec splénomégalie [Value of Splenocontraction in Treatment of Chronic Malaria with Enlarged Spleen.]—*Ann Soc Belge de Méd Trop* 1933 Sept 30 Vol 18 No 3 pp 501-507 [24 refs.]

With experience of some twenty recently treated cases the author writes enthusiastically of the value of Ascoli's method of treatment which he regards as a most important addition to malaria therapy. He confirms the favourable results obtained by many other workers. N IV

RUSSELL (Paul F) Malaria due to Defective and Untidy Irrigation. A Preliminary Discussion.—*Jl Malaria Inst of India* 1939. Dec Vol 1 No. 4 pp 339-349 With 22 figs. on 11 plates [22 refs.]

Interesting quotations from reports some of which are nearly a hundred years old show with what persistence the association of irrigation with malaria has been stressed by public health workers. In spite of this the author's observations have led him to believe that the situation as regards malaria and irrigation is probably worse to-day than ever before irrigation malaria not only persists but is being made a greater problem each year.

During the last 80 years the Government of India has spent a hundred million pounds on irrigation projects crops raised on land thus irrigated are now worth some 66 million pounds a year. India has been a leader in fundamental research in irrigation and in every aspect of malariology. There has been almost complete failure to integrate in practice these two subjects.

It is not irrigation but defective irrigation that produces malaria. The author has been engaged on the study of this problem in a part of the Tanjore District in the south of the Madras Presidency [see this *Bulletin* 1939 Vol. 36 p 131]. He has on his staff an entomologist a physician trained as a malarialogist an agronomist investigating the relationship between farming irrigation and malaria, and an engineer

with experience of irrigation and agricultural engineering. Attention is called to the following malaria producing defects in construction, operation and maintenance of an irrigation system, all of which are well illustrated by photographs—defective sluice gates seeping canal banks borrow pits defective distributing chambers excessive supply of water frequently seen in canals improper delivery of water into a roadway or ditch for example improper maintained canal banks and canal beds absence of any planned or controlled system of field channels insufficient number of bridges across canals perhaps the most important defect cutting off drainage canals perhaps the most important defect absence of water caused by a barrage and general untidiness. In the district under study, a dry tank has become a wet one during the irrigation season, rice is now cultivated fallow fields remain wet for a longer time than formerly rivers and tanks carry more water and are empty for a shorter time the subsoil water has risen wells which formerly contained water to a level of 35-40 feet below ground now have an average water level of less than 10 feet and in some seasons less than a foot below ground level unplanned streams and channels have become numerous ditches are full of water as are borrow pits, throughout the irrigation season. Engineers cannot be held responsible for all these undesirable products of an irrigation system. Detailed specific corrective or preventive technique for dealing with irrigation malaria will be considered in future publications. In the meantime the author urges the need for organization and co-operation of the many agencies interested, especially for more active and more practical co-operation between malariologists and irrigation engineers.

AFANASSIEV (S F) The Employment of the Distillate of Coke Filters for the Destruction of the Larvae of *Anopheles maculipennis* Preliminary Communication.—Med Parasit & Parasitic Dis Moscow 1938. Vol 7 No 5 [In Russian pp 694-700]

The object of the experiments recorded in this paper was to test the efficacy of a cheaper substitute for petroleum in combating anopheline larvae. The author employed the distillate of coke filters obtained in the final stages of fractional distillation of Russian petroleum. The distillate is composed of heavy oils (including solar oil) and represents a mixture of various hydrocarbons, mainly aromatic compounds.

In a laboratory experiment the distillate sprayed over the surface of the water in a vessel containing 60 larvae of *A. maculipennis* killed all of them in one hour. When applied to natural reservoirs containing mosquito larvae the distillate caused the destruction of all the larvae and of other aquatic animals, except crustaceans and Gambusia, in 24 hours. It is concluded that the distillate provides a satisfactory substitute for petroleum and can be used for oiling in the same doses (from 25 to 50 grams per square metre, according to the amount of vegetation present).

C 4 Hours.

ROY (D N) On the Control of Malaria-Mosquitoes in Bengal by the Use of Predacious Fish and on the Habits of Two of them.—*Jl Malaria Inst of India* 1933 Dec. Vol 1 No 4 pp 405-416 [11 refs.]

Observations on the habits of two small fish common in Bengal are recorded —*Panchax panchax* and *Barbus phutunio*. The first named is the most useful of the indigenous species in antilarval work. The author concludes however that the rôle it plays is of very limited value. *A. philippinensis* and *A. varuna* are the two tank breeding vectors against the larvae of which the fish would be expected to be most effective. During the malaria transmission season the tanks in Bengal are heavily overgrown with vegetation the presence of which affords protection for the larvae against the depredations of fish

- 4 HIRST (L. F) Hookworm Disease and Ceylon Sewage Works.—*Ceylon Jl of Science* Sect. D Med Science. 1932. Vol. 2. No. 5 pp 245-275
Abstract taken from *Biol. Abst.* 1933 No 18832.

A remarkable outbreak of dermatitis occurred in May 1919 among a gang of 11 coolies digging trenches in which sludge from septic tanks had been buried at least 3 years before. While no explanation is available for this initial outbreak, the author's studies here on sludge and effluents from central sewage treatment works and in controlled experiments contain numerous observations of interest in this field. Ova closely resembling *Necator americanus* have been found in the silt of the main sewers and

snaps of the pumping station the highest count being 250 eggs per gm. of sludge (DCE). Hookworm larvae were only occasionally detected in the main drainage system, though larvae of free-living nematodes were common. Sludge from the two-story septic tanks of the main treatment works yielded a mean count of 23 hookworm ova per gm. (infective larvae were cultured from this sludge) as well as many *Ascaris* and *Trichuris* ova. The highest count of hookworm eggs obtained from sewage entering these tanks was 330 per litre though typical hookworm larvae were seldom detected here. It is very roughly estimated that 1/3 of the hookworm ova passed by the population of Colombo City reach the septic tanks of the sewage treatment works in a recognizable condition. In an experimental sewage treatment plant the rate of elimination of hookworm eggs from avian sewage (2-100 minutes) was studied in the effluent of 3 double-story Imhoff pattern tanks in series. A characteristic test showed that passage through the first of 3 similar tanks reduced the hookworm ova in a representative 24-hour sample of sewage to 1-9% of the original count of 15,500 per litre. The effluent from the second tank showed a further reduction to 0-8% the third tank to 0-4. About 30 hookworm eggs per litre were present in the final effluent after passage through 3 tanks in series and a rubble bed during a flow through period of 41 hrs. *Ascaris* and *Trichuris* eggs were also very much reduced, although the quantitative test applied is not to be considered as accurate. The rate of elimination of hookworm eggs at each stage of the treatment was correlated with that of the suspended solids. Attempts to accelerate the death rate of ova in drying sludge through the use of de Smet's boxes (entrapping solar heat), were promising. Suggestions are made for the design and operation of sludge pans with a view to combining the functions of drying and heating to the best advantage.

- 5 VASANIKOVA (Z.) Sur la déhelminthisation des eaux d'épuration par méthodes intensives.—*Medical Parasitology & Parasitic Diseases* 1938 Vol 5 No 5 pp 657-673 [In Russian.]
Abstract taken from Dept Secret & Indust Res Water Pollution Research Summary (Current Literature 1938 Nov No 1529)

Sewage and sludge from the biological purification plant of Tula, and from the aeration plant of Kopezhkov (Alo-cow) were examined for helminth ova. Over 2,000 ova belonging to 5 species were found per litre of crude sewage. The Imhoff tanks removed 97 per cent of these ova, and the secondary sedimentation tanks 87 per cent of the remainder. Biological filters only reduced the numbers by 18-28 per cent. Chlorination did not affect the vitality of the ova. The sludge contained up to 468 ova per gm. 20 per cent of these were destroyed by anaerobic digestion. In sludge kept in the open the ova did not disappear completely for 3 years. To obtain better removal of the ova the author advises longer periods of settling filtration through sand, and an increase in the temperature of the digestion tanks to 45°C.

REVIEWS AND NOTICES

SCOTT (H Harold) [CMG MD FRCPLond DPH DTM & H
Camb FRSE Director Bureau of Hygiene & Tropical
Diseases etc] *A History of Tropical Medicine Based on the
Fitzpatrick Lectures Delivered before the Royal College of Physicians
of London, 1937-38* Vol. 1 pp vii+1-648 Vol. 2 pp ix+
649-1165 With 13 plates 1939 London Edward Arnold &
Co [Two Vols. 50s]

This great work is based on the Fitzpatrick Lectures which the author delivered before the Royal College of Physicians in 1937-38. A careful perusal of the preface will enable the reader to form some conception of the task which Scott has undertaken. Here we read

With regard to choice of subject in my case fortunately there was no difficulty the difficulty is in the fulfilment. Here and there scattered in medical works dealing with diseases in the tropics we find a few notes on the history of these diseases but speaking in any sense other than the narrowest there is no history of the rise and development of tropical medicine and yet the subject is of absorbing interest. It is a most fascinating occupation to study the early vague empirical ideas as to the causation of a disease to trace the beginnings of rational thought thereon the interpenetration of scientific notions and empiricism the progressive clarification of the haze of doubt to the final solution of the problem.

In the case of so-called Tropical Medicine the difficulty has been the greater because it has necessitated tracing back in some instances to times of savagery the earliest available records and to legends prior to record. In others the first traces had to be sought in articles in books in references in foreign languages works attainable with much difficulty and often only in garbled or mutilated copies the originals of which had been lost.

Another and very real difficulty with which the author was confronted is that we have no definition of the term Tropical Medicine. He shows that if we accept its narrow interpretation as diseases restricted to the tropics we could with close approximation to the truth say that it is non-existent. If the interpretation be extended to diseases met with in warm climates we have to include nearly all the ills that flesh is heir to and almost equal difficulties are encountered if it be decided to deal with *prevailing diseases* in warm climates. The task which the author has set himself is not to give a history of diseases of warm climates but a history of tropical medicine

in the generally accepted sense the former would have necessitated going over ground already well covered—a discussion of malaria, plague and perhaps other diseases from the dawn of history—but the latter is the rise and development of tropical medicine. Its starting point is the time when reason began to throw its light upon and illumine the darkness of empiricism, when people began to theorize regarding causation of disease to consider the problems scientifically and that rarely takes us back more than a hundred to a hundred and fifty years. The author has, however frequently found it necessary to select times long antecedent to this, because some of the modern idea on aetiology, pathogeny and treatment originated in ancient empiricism and their history would be incomplete if such were disregarded.

The general plan which Scott has left before him in writing this History is as follows.—As a preliminary he describes from the medical point of view the state of some of the countries when they first came under European rule and by this means indicates the nature of the problems which arose and the conditions under which their solutions had to be undertaken. He then traces how improvements have been brought about usually starting with the health of the natives, be officials and traders, and subsequently with that of the natives, he shows how local preventive measures have expanded to include public health on a wider scale how philanthropy has made an ever increasing claim on the governing race, and finally how the welfare of the native has come to take first place.

Such is the task which Scott has set himself and how well he has accomplished it the reader must judge for himself as it is quite impossible for a reviewer to give more than a bird's-eye view of the contents of these two large volumes.

The first two chapters deal with the progress of hygiene in the East and Mercantile Marine from the early days when commerce with all and the lot of the sailor quite a secondary consideration, and with the conditions under which the soldier lived during the eighteenth and nineteenth centuries. Chapter 3 depicts the conditions of the people and the prevailing diseases of a century or a half ago tropical and subtropical colonies to which they were liable in the and Chapter 4 deals similarly with India and Australasia. These four chapters, which are copiously illustrated by most interesting and pertinent quotations, make fascinating reading.

Chapters 5 to 18 are concerned with great diseases of the tropics, viz.—malaria, blackwater fever, yellow fever, trypanosomiasis, leishmaniasis, leprosy, cholera, plague, undulant fever, relapsing fever, melioidosis, dengue, amoebiasis, ankylostomiasis, and the tropical diseases connected with food. It may at first sight seem that of all the worm diseases ankylostomiasis alone finds a more formidable list. But Scott tells us that it is the only one of sufficient interest to call for any detail. world of course be presumptuous for any reviewer to express opinion whether these chapters give an adequate and accurate out of the history of all the great diseases with which they deal, doubtless there are individuals who have made a historical study one or two of them, but it would require the united efforts of many such experts to produce a critical review of any value of volumes covering such an immense field.

But although the present reviewer must freely admit that he has no expert knowledge of the history of any of the important tropical diseases the fact that he has, since the first appearance of this *Bulletin* been responsible for the summaries of blackwater fever and sleeping sickness papers entitles him to claim some acquaintance with the literature of these diseases. It was consequently with special interest that he examined the chapters devoted to them and he was well repaid. Something was learned much that was half forgotten was recalled to mind and wherever statements and data were tested they were found to be accurate.

Next follow three delightful chapters devoted to the Suez Canal the Panama Canal and the slave trade and disease and finally there is a chapter consisting of brief sketches of the lives of a few of the more important or better known of those who have devoted their chief interests to tropical medicine viz Bontius Bruce Carroll Cruz Dutton Findlay Garcia da Orta Gorgas Lazear Leishman Lind Manson Noguchi Reed and Ross. As is shown by the names selected for this special notice and by the list of authors consulted which is given at the end of the volumes Scott has not failed to give due credit to workers of all nations.

The reviewer finds it quite beyond his powers to do justice within the compass of a short review to this monumental work which is truly remarkable not only for its wide learning but equally for its general interest and the delightful manner in which its stories are told. It is doubtful whether anyone but the Director of the Bureau of Hygiene and Tropical Diseases could have written such a book and it is certain that everyone who acquires these two volumes will read them with pleasure and with profit.

AMSTERDAM. *Acta Conventus Tertii de Tropicis Atque Malariae Morbis. Pars I. Acta Conventus Tertii de Tropicis Morbis.* 720 pp. III. *Pars II. Acta Conventus Tertii de Malariae Morbis* [Transactions of the Third International Congress on Malaria and Tropical Diseases]—601 pp. III. 1938. Amsterdam Societas Neerlandica Medicinae Tropicae.

Neither of these volumes can be reviewed in the accepted sense of the term. Each contains matter of great scientific value and should be kept for reference as denoting the state of knowledge towards the end of 1938 of the many subjects dealt with.

Previous Congresses in Tropical Medicine had been held in 1913 and 1928 and the third was arranged for 1932 but had to be postponed. Malaria Congresses had been held in Rome in 1925 in Algiers in 1930 and a third was to take place in Madrid in 1935 but it too had to be postponed owing to the unrest in Spain. The two Congresses were, therefore held simultaneously in Amsterdam in September 1938 under historical conditions of great political unrest and in fact were nearly brought to naught after the first two days on that account.

These two volumes record the papers read—more than a hundred in all—and the discussions which arose out of them. Some sixty in Volume I deal with tropical conditions the chief of which are deficiency diseases filariasis, plague and yellow fever and forty two in Volume II with various aspects of malaria its epidemiology parasitology treatment and control in different countries.

Professor C. D. DE LANGE undertook the task of editing all these for publication together with giving an account of the introductory and concluding ceremonies and addresses—a task which must have entailed much misnomers and real hard work, but which has been accomplished in a way which could not have been surpassed. To him, therefore are due the very hearty congratulations and thanks of all those who attended the Congresses and who have thereby become recipients of these excellent volumes of reports.

PETROV (V. P.) *Kala Azar (Visceral Leishmaniasis)* Thesis for M.D. Medical Institute Tashkent 260 pp. With 71 figs. [880 refs.]
In Russian pp 1-258. English summary pp. 259-263.]

This publication, representing the author's thesis for M.D. is actually intended to be a text or handbook on kala azar. In illustrating various aspects of the disease the author has drawn largely upon his own clinical experience (857 cases) a course which will probably be appreciated by Russian physicians practising in the affected areas of U.S.S.R. Since some of the data relating to the country are scattered in various publications and are sometime inaccessible they will be briefly summarized here for the benefit of those not conversant with the Russian language. The first chapters are devoted to the history and distribution of kala azar in the Soviet Union this disease occurs east and west of the Caspian sea in Transcaucasia (Armenia, Georgia and Azerbaïdjan) where 300 cases have been recorded, and in Middle Asia (Tashkent, Kerki, Samarkand, Katta-Kurgan, Bahmansabz, Bokhara, Tcharcho-Kerki, Ashkhabad, and in the Kushka, Takhta-Bazar, Kashka-Daria, Serkhan-Daria and Andijan districts) with about 2,000 cases. Oriental sore and canine leishmaniasis occur in the same regions sometimes in separate foci, sometimes overlapping the areas of distribution of kala azar. (The distribution of leishmaniasis in U.S.S.R. is illustrated by a map.) Chapters 3 and 4 deal with the aetiology and transmission of kala azar. The most important vector in Middle Asia is *Phlebotomus papatasi* in addition to which the following fifteen species have been recorded in U.S.S.R. *P. argenti* *P. var. alexandri* *P. caucasicus* *P. squamipennis* *P. major* *P. chinensis* *P. subarcticus* *P. venosus* *P. perillatus* *P. pautouvi* *P. kandelaki* *P. borovskii* *P. griseus* *P. segniensis* *P. minor*. In chapters 5 and 6 an account is given of the epidemiology and clinical course of kala azar. Like some other Russian workers the author believes that canine and human visceral leishmaniasis are intimately connected. In Middle Asia the seasonal incidence of kala azar coincides with the winter and spring months. The disease is more common in children under 6 years (about 80 per cent.) The age-distribution is thus similar to the highest (58.8 per cent.) The next chapter (7) deals with the methods of diagnosis. For direct examination the author strongly recommends gland and smears punctures, in preference to spleen puncture as regards serological methods he has obtained consistently good results with complement fixation, while the various biochemical reactions were found to be unreliable. The last three chapters (8, 9, 10) are devoted to pathology, therapy and prophylaxis. There is an extensive bibliography including 219 Russian references. The handbook will be of real value to Russian practitioners in the endemic

regions while the foreign reader will find in it useful local data some of which have been briefly mentioned above. The author is not to be blamed for the external appearance of the book, the poor quality of the paper and the defective reproduction of some of the illustrations.

MEIJER (Trans Hendrik) *Onderzoek van vibriosen uit Nederlandsch Indië en den Hedjaz*. [Examination of Vibrios from Netherlands India and the Hedjaz] [Thesis for Doctorate of Medicine at Amsterdam University]—155 pp With 1 plate [9 pages of refs] English summary 1939 N V Uitg Mij C A J van Dishoeck Bussum

The title of this thesis does not fully indicate the scope of the monograph which is very largely devoted to a critical examination of the El Tor vibrio question. That question forms at the present time one to which it is very desirable that a satisfactory answer should be given and it is the endeavour of the author to prove that the El Tor produces a different disease from the cholera vibrio. He has considered and included a great deal of the work of others in his thesis while his own work is skilfully interwoven with the text of the several chapters. These chapters comprise—Introduction. Technical methods. Vibrios isolated in Batavia. Strains isolated at Mecca. Recognition of the cholera vibrio. Diseases caused by vibrios other than the cholera vibrio. Summary and conclusion. The summary and conclusion which is in French and English as well as in Dutch represents a great deal of the author's own opinions and work. A long and very useful bibliography completes the thesis.

In Batavia 20 444 samples of faeces were examined and these were divided into one group of 14 854 sound persons that is to say with no abdominal condition and a group of 5 590 patients. A further group was constituted by samples of surface and well waters. The healthy group provided 54 vibrios and the patient group 46 vibrios. Not a single typical agglutinable El Tor vibrio was found. The vibrios isolated from the patient group in contrast to the healthy individual group and the water group was very homogeneous. All the strains of the group gave a positive cholera red reaction liquefied gelatin in 1 to 3 days showed haemolysis in blood broth usually in one day and for the greater part did not ferment mannose and arabinose.

Of the vibrios isolated in Mecca 14 were from water and 11 from faeces. One of these M 28 was a typical El Tor vibrio belonging to group I of GARDNER and VENKATRAMAN. It came from the well known Zam Zam well. All the other Mecca strains gave much the same reaction as the Batavia patient group.

Haemolytic power is one of the chief features by which the El Tor and most of the water vibrios may be distinguished from the true cholera vibrio. It has again been shown that this property remains constant. If blood be added to bouillon cultures of haemolytic vibrios those which have been incubated for 24 hours only at 37°C show haemolysis but with the increase of the incubation say to 5 days the addition of blood is no longer followed by haemolysis. One explanation of this is that haemolysin (exohaemolysin) is destroyed by the digestive ferment possessed by vibrios. Even the true cholera vibrio is haemodigestive when freshly isolated. Haemodigestion therefore has to be taken into account in determining haemolytic effect of an

El Tor vibrio and even of water vibrios. This difficulty can be got over by using blood bouillon instead of solid media for test, because in this case digestion does not take place. DR MOOR found that haemodigestion only took place in the presence of oxygen and devised the method of incubating blood agar plates *in vacuo* to get rid of the disturbing effect of digestive action. Thus he did in determining the character of what is now called *V. cholerae*. Still another method of separating the two properties of haemolysis and haemodigestion is that of VAN LOGHEM, who found that all vibrios having digestive power lose it slowly with continued subculture. van Loghem also explains the so-called late haemolysis of the cholera vibrio as due to an endohaemolysin not an exohaemolysin and accounts for its appearance by the liberation of endotoxin with the death of vibrios. Its appearance can be delayed by delaying the death of the vibrios. In his own work the author confirms what is called the phenomenon of CHAPEX who claims to have discovered a serological difference between *V. El Tor* and *V. cholerae*. A suspension of the former heated for 3 hours at 56°C. still remains agglutinable, whilst the latter becomes magglutinable. A similar result is obtainable by treating suspensions with chloroform. "Finally the toxicity in regard to the white rat is a point of difference between the two vibrios. Intracutaneous injection of cholera vibrios produces little or no effect but necrosis and inflammation follow the injection of El Tor and water vibrios.

It is still a matter of uncertainty how far the El Tor vibrio is to be reckoned with as a producer of disease. Such disease as it may produce seems to be quite independent of cholera. This leads the author to maintain "that enteritis choleraiformis El Tor is not the same disease as cholera and consequently the international regulations laid down for cholera are not applicable to the El Tor disease." SUMMARY OF RECENT ABSTRACTS

VIII TYPHUS GROUP OF FEVERS *

[It has not been found possible to adopt a satisfactory method of classification for the work here summarized. General information and work on vaccination have therefore been collected into a separate section followed by sections on (1) the group predominantly positive to *Proteus* O\19 (vectors louse and flea) (2) that positive to O\K (vector mite) and finally (3) the indeterminate group (vector tick). These sections, however cannot be rigidly separated.]

General

The classification of the typhus group of fevers is not yet satisfactorily settled. BURNET (p 356) suggests a provisional classification of the Rickettsial diseases which though depending largely upon the vectors is not rigidly confined to that method. This scheme is not based upon serological reactions. He points out that in true typhus man is principally involved, whereas in other typhus-like fevers man is only occasionally involved.

OCHI (p 792) describes a method for staining Rickettsia in sections which cannot be further abstracted

Vaccination

PARROT (p 368) differentiates between true immunity in which as in scarlet fever the organism disappears completely from the body but immunity remains and premunition in which there is protection so long as living organisms remain as in syphilis. In the latter the reticulo-endothelial system is involved. The proof of the existence of premunition is detection of the parasite in the resistant body. This is difficult in rickettsial diseases but may be accomplished (1) by inoculation of blood into susceptible animals (2) by the feeding of vectors on animals, or (3) by splenectomy or reticulo-endothelial blockage followed by relapses. By these methods certain rickettsial diseases have been shown to produce premunition and by analogy it is suggested that certain diseases of the typhus group may do the same. Since therefore the presence of living organisms is necessary for protection

The information from which this series of summaries has been compiled is given in the abstracts made by the Sectional Editors in the *Tropical Diseases Bulletin* 1938 Vol. 35. References to the abstracts are given under the names of the authors quoted and the pages on which the abstracts are printed.

in diseases giving rise to premunition, vaccines for typhus must be prepared with living virus. In non-epidemic periods, it is possible that some interference with the reticulo-endothelial system in persons in whom the virus is latent may result in parantic relapse with infection of lice, thus forming a starting point for an epidemic outbreak.

For the culture of typhus *Rickettsia* ZIKSSER *et al* (p. 363) used 4 per cent agar with equal volume of double strength Tyrode solution to which 50 per cent horse serum had been added. Growth appeared on the slope in 6 days. Later (p. 784) they employed a modified agar medium (q.v.) with mouse embryo tissue for the culture of *Rickettsia*. These cultures can be used for the preparation of vaccines. BENGTSON (p. 373) prefers Baker's solution to Tyrode's solution in Maitland's medium for the cultivation of the *Rickettsia* of Rocky Mountain fever [*R. rickettsii*]. She subcultured successfully for 14 generations and 81 per cent of animals inoculated from time to time reacted to the virus. There was no loss of virulence. The *Rickettsia* were seen in the cytoplasm, but not in the nuclei, of the cells. Similar success was obtained (p. 363) with the viruses of endemic and epidemic typhus. BARYKIN *et al* (p. 784) inject infective material into the yolk of eggs near the embryo and incubate at 32°C. Large amounts of virus are obtained.

In the *Bulletin of the Health Organisation* (League of Nations) (p. 357) are set down the findings of a Committee engaged on the consideration of vaccination against typhus. Living vaccines confer earlier and greater protection than killed vaccines and should be used in the presence of an epidemic. In a country free from the disease however it is wiser to avoid the introduction of living virus and killed vaccines should therefore be used if prophylaxis is considered necessary. Standard methods of licensing should be organized and carried out vigorously.

A considerable fall in the mortality rate of Rocky Mountain fever in the north western United States in recent years is attributed by HAMPTON and EURANK (p. 800) to the extensive use of vaccine.

In experiments on guinea-pigs NOURY (p. 370) found that killed vaccine gave no protection against typhus.

In Tunisia LAIGRET *et al* (p. 784) used a living vaccine of endemic typhus virus dried and suspended in egg yolk and finally in olive oil. In 30 000 persons vaccinated in 1936 in areas where typhus existed, only 3 cases occurred in that year and none in 1937 though cases were found in the non-vaccinated. The three measures taken were isolation, leaving of contacts and vaccination, the advantage of the latter being that normal life can be continued. SCHÄFER (p. 370) obtained good protection in mice with 2 doses of living virus emulsified in egg yolk and in oil. Dried vaccine similarly emulsified was not nearly so effective.

The Weigl killed vaccine prepared from lice was used near Lwow and RADLO (p. 783) states that about 80 lice intestines are prepared for each person, given in 2 or 3 doses. To check an epidemic it is enough to vaccinate 30 per cent of the population.

BLANC and BALTAZARD (p. 384) found that faeces of fleas infected with murine virus, carefully dried *in vacuo* may be infective for 100 days. Four volunteers were immunized by a vaccine of such faeces treated with bile. GAUD (p. 793) shows that after an extensive campaign of vaccination against typhus by the method of Blanc the number of cases of typhus which had assumed epidemic proportions,

in N. Africa was greatly reduced. No severe reactions were seen. BONJEAN and NAIN (p 368) found positive Weil-Felix reactions in 96 of 111 persons recently vaccinated against typhus with bile-treated vaccine.

CASTANEDA (p 369) found that the phenomenon previously observed by ZINSSER and himself that irradiation of infected rats produced large numbers of rickettsial bodies in the peritoneal fluid from which vaccines could be prepared does not occur if the rats are kept at over 38°C.

BENGTSON (p 374) prepared a vaccine to which was added formalin in the proportion of 0.1 per cent from cultures in modified Maitland's medium. This proved effective in guinea-pigs.

KLIGLER and LEVINE (p 795) use two-week-old tissue cultures of typhus *Rickettsia* triturated and suspended in saline and formalized for vaccination. Monkeys and laboratory workers developed positive Weil-Felix reactions after vaccination without discomfort or rise of temperature.

Proteus O119 type Vectors louse and flea

Having previously isolated *Proteus* V19 from the blood of 50 per cent of patients in a small outbreak of typhus SPARROW and ROUSSEL (p 367) repeated the attempt and succeeded in only 2.8 per cent of 309 Weil-Felix positive bloods. They also isolated the same organism from 6 per cent of 100 bloods from patients with fevers other than typhus.

GIROUD and TANNENBAUM (pp 368 and 792) show that *Proteus* though common in the intestine of man and rabbits is not found in guinea-pigs and that the latter do not give positive Weil-Felix reactions on infection with typhus but do so if *Proteus* has previously been introduced into the alimentary canal. They suggest that the Weil-Felix reaction is due to the passage of *Proteus* into the blood during an attack of fever.

Although mice may be easily infected by large intraperitoneal doses of the virus of endemic typhus OKAMOTO (p 370) found that with the same technique only 2 of 412 mice showed *Rickettsia* when the virus of epidemic typhus was used.

By inoculating dilutions of emulsions of organs of animals infected with typhus into the skin of rabbits GIROUD (p 791) showed that the tunica which gives a nodule in dilutions up to 1/2000 contains 10 times more virus than other organs. Cultured virus gave less marked reactions than passage virus.

BALTAZARD (p 795) quotes the work of NICOLLE to show that typhus virus mixed with immune serum does not infect and shows that when treated with bile the viruses of murine typhus and boutonneuse fever fail to provoke local reactions. In researches on sera from persons with Rocky Mountain fever and typhus conducted with murine and boutonneuse viruses he has found that the serum of persons or animals cured of typhus or murine typhus prevents local reaction by murine virus and that serum from boutonneuse and Rocky Mountain fever prevents local reaction by boutonneuse virus. GIROUD (p 790-791) shows that serum from patients recently recovered from typhus mixed with the virus for 30 minutes prevents reaction on injection into the skin of the rabbit. Normal serum does not. This test may be used to demonstrate antibodies in the blood. On the other hand he shows (p 791) that serum from persons who have received inoculations

of killed virus not only does not prevent reaction when mixed with living virus and injected, but also leads to a more severe reaction than is found with normal serum. WEIGL (p 785) however states that the serum of convalescents if mixed with virus can prevent infection in animals. The serum of recently vaccinated persons is equally effective and if given together with vaccine during the incubation period of typhus, fever is prevented and immunity due to the vaccine is developed. Contacts may be protected in the same way.

GEAR and BECKER (p 787) describe in detail the course of a case of typhus accidentally acquired in a laboratory. The incubation period was one week, the rash appeared on the 5th day of fever, there was a crisis on the 13th day, leucopenia was present and the Weil-Felix reaction was positive to *Proteus OX19* only. There was no true primary sore as in tick bite fever.

WU and ZIA (p 785) conclude that there are two types of *Rickettsia* in Peiping, one resembling the endemic type and giving scrotal swellings in guinea-pigs, the other resembling the epidemic type with which these swellings do not occur but which regularly produces typhus nodules in the brains. Complete cross immunity was found between the former and the Mexican strain, but not between the epidemic type and the Mexican strain. DELBOVE and NGUYEN VAN HUONG (p 364) showed that two strains isolated from rats in Saigon produced fever and (in half the tests) scrotal reactions in guinea-pigs. By cross immunity tests it was found that 3 strains were immunologically identical with the Peking strain of epidemic typhus. Between 8 and 9 per cent of the sera of 1 015 rats gave positive Weil-Felix reactions, mostly with *Proteus OX19* but some with OXA. The percentage rose to 20 in June and fell to 6 in April and May.

Of 50,000 patients in Peiping in recent years, 450 were diagnosed as suffering from typhus and in a high proportion the serum agglutinated *Proteus OX19* in a dilution of 1,280. Typhus nodules in the brains of 10 studied by CHUNG and CHANG (p 783) were numerous. One case is reported in detail. The Weil-Felix reaction was positive for *Proteus OX19* 1 in 1,280. Guinea-pigs inoculated with blood developed fever but no orchitis, body lice injected into guinea-pigs produced fever, clean lice fed on the patient were heavily infected with *Rickettsia* and produced fever in guinea-pigs, and *Rickettsia* were found within the cells of lice intrarectally infected with guinea-pig brain emulsion. These findings point to true epidemic typhus.

RAYNAL (p 781) shows that louse-borne relapsing fever is common in Shanghai and reports 14 cases of typhus with positive reaction to *Proteus OX19*. These are also probably louse-borne.

DRPOMLAV (p 781) describes the measures taken against typhus in Czechoslovakia. APPEL (p 799) points out procedures whereby notification, disinfection and isolation can be more effectively carried out than at present in the department of Constantine. These cannot be further abstracted. CHI and SU (p. 799) describe a simple hot air delousing box in which lice and mites can be killed in 20 minutes.

GRAY *et al* (p. 788) describe the first case of sporadic typhus in Bristol for 10 years. Serum agglutinated *Proteus OX19* but not OXK. No virus could be isolated from rats captured near the man's work place, a mill. In the *Irish Journal of Medical Science* (p 306) is a record of a man diagnosed as suffering from typhus in Cork city. The Weil-Felix reaction was negative on 3 occasions but clinical evidence

was convincing Typhus has not been recorded for 8 years but may exist in the rat population still

LE CHUITON *et al* (p 782) on the assumption that the virus of murine typhus was present on bread contaminated with the urine of rats in Toulon harbour and that outbreaks among members of the crews were due to this fact caused the bread which had previously been left exposed on the tween decks to be carefully stored and found that the numbers of cases of the disease fell from 34 in 1935 to only 4 in 1937 [see VIOLE below]

MODINOS (p 360) describes a case of murine typhus in Egypt in which agglutination of *Proteus* X19 was present and blood produced fever and orchitis in a guineapig. An animal previously inoculated with a known typhus virus was found to be immune to blood from this patient. Cases of true typhus and boutonneuse fever are also described. Near Tunis DURAND (p 360) discovered a patient with murine typhus. The virus produced fever and orchitis in guineapigs and there was cross immunity between this virus and that of true typhus and that of murine typhus but not with the virus of boutonneuse fever. Agglutination of *Proteus* OX19 took place at 1 in 16 000 dilution.

DURIEUX and ARQUIÉ (p 361) show that murine typhus may be a fatal disease and record one death in 4 cases occurring in Dakar. *Proteus* OX19 was agglutinated at 1 in 500 dilution and fever and orchitis produced in guineapigs.

Two cases giving positive reactions with *Proteus* X19 are recorded by MONTRESTRUC *et al* (p 362) from Martinique. A single case of typhus in which *Proteus* OX19 and OX12 were agglutinated is reported by GOSDEN (p 381) from Trinidad. No others have been reported for many years.

HSEIH *et al* (p 362) report 14 cases of typhus from Changsha. All recovered and were probably of the murine type.

In the *Public Health Notes* Adelaide (p 363) it is stated that endemic typhus in South Australia is the same as that found elsewhere but it has not yet been possible to isolate the virus.

GOURIOU *et al* (p 789) report phlebitis of the leg in a patient with endemic typhus. This has not been recorded before though it occurs in boutonneuse fever.

With the virus of murine typhus GIROUD (p 796) found that in mice rats guineapigs and rabbits general susceptibility is inversely proportional to local reaction. This may be shown in tabular form —

	General susceptibility	Local reaction
Mice	High fever	Nil
Rats	Fever not so high	Nil
Guineapigs	Mild fever	Definite
Rabbits	Not apparent	Marked

KASAHARA *et al* (p 784) filtered tissue cultures and emulsions of organs from guineapigs infected with murine typhus through Berkefeld filters and demonstrated Rickettsia in smears from the tunica of guineapigs inoculated with material from rabbits which had received injections of the filtrate.

BLANC and BALTAZARD (p. 785) found that the minimum infective dose of murine typhus virus in louse faeces was at least 100 times greater for the guineapig than for man.

RIDING (p. 360) has isolated a virus obtained from the brains of 4 wild rats caught near Cairo. Fever and orchitis were produced in guineapigs and infected rabbits developed positive Weil-Felix reactions. ZWIERS (p. 786) found that 16 per cent. of the sera of rats from endemic typhus areas in Poland gave positive Weil-Felix reactions. The virus gave fever but no orchitis in guineapigs.

In the southern United States, BRIGHAM and DYER (p. 782) have found opossums, field mice, rats and the flying squirrel to be susceptible to the virus of endemic typhus. They isolated it from one field mouse.

VIOLLE (p. 786) shows that young pigs can be infected by ingestion of the virus of murine typhus and of boutonneuse fever the latter producing a rash and (p. 371) records the infection of a young pig with the virus of endemic typhus, with the development of a macular rash which became petechial. VIOLLE and SAUTET (p. 786) failed to transmit murine typhus to rats by the bite of *Triatoma infestans* but succeeded when the bugs were crushed and ingested by the rats. VIOLLE (p. 372) infected a dog by feeding with the brain of a guineapig infected with murine typhus. The Weil-Felix reaction was negative but the blood of the dog was infective. He suggests that infection may be conveyed to man by food contaminated with the urine of rats [see LE CHURTON *et al.* above]. He considers that the wild rabbit may be a reservoir of this virus. Intradermal injection of small doses of virus into rats and guineapigs is useful in rapid diagnosis.

Noting that guineapigs receiving the virus of Tunisian murine typhus by instillation on to the conjunctiva acquire immunity though no severe infection results, SPARROW and MARESCAL (p. 794) applied the same technique to 5 men. All developed mild fever without rash, in 15 days the Weil-Felix reaction became positive and all were proved to be immune.

Proteus OAK type Vector mite

Twenty cases of scrub typhus mostly positive to *Proteus OAK* and negative to *OAK 19* are reported from plantations in Cambodia by DELBOVE *et al.* (p. 780). All occurred in male coolies engaged in clearing scrub and in the rainy season when the rodent population was driven by floods to the high ground where the men were working. ALAIN and DELBOVE (p. 781) record 4 cases of fever which they regard as closely allied to Japanese river fever observed in Indo-China. Three gave positive reactions with *Proteus OAK* all showed primary sores and generalized maculo-papular rash. Guineapigs inoculated from one developed fever but no scrotal reaction.

KAPILA and MAITRA (p. 358) describe a patient in India with severe fever, enlarged glands and a rash. The Weil-Felix reaction for *Proteus OAK* was positive on the 15th day.

SHORTT (p. 779) reports that 68 of 134 squirrels in Madras gave positive Weil-Felix reactions with *Proteus OAK* from 1/25 to 1/200 dilution. No positive results were obtained from the examination of ectoparasites or from 90 bandicoots.

VAUCEL and BRUXEAU (p. 383) cultivated 22 strains of *Proteus* from the blood of 288 rats in Hanoi. Only one was fully identified as *Proteus OAK*.

KAWAMURA *et al* (p. 374) have used the virus of the mild form of tsutsugamushi fever seen in the Pescadores for fever therapy in the treatment of nervous diseases. Symptoms produced were slight and 8 days later inoculation of the potent Japanese virus resulted in a mild reaction only. There was slight improvement in the mental condition.

RAGIOT *et al* (p. 788) note that although there are two clinical types of typhus in Indo-China, one with rash and primary sore and one without, the viruses of the two types are apparently identical, resembling those of Rocky Mountain and São Paulo fever and producing agglutinins to *Proteus* OXA but not OX19. Guinea-pigs inoculated with the virus of scrub typhus isolated in Saigon by DELBOVE and NGUYEN VAN HUONG (p. 785) showed results resembling those produced by Rocky Mountain fever rather than by tsutsugamushi fever and were not rendered immune to the Peking typhus virus.

In the Simla hills there occur two waves of typhus. One in winter in which sera agglutinate *Proteus* OX19 and one in August-October in which sera agglutinate *Proteus* OXA. SMITH and MEHTA (p. 358) investigated the serological reactions of 1212 wild rats caught from May to February and found a marked increase in OXA agglutinins from October to December. No result was obtained in attempts to infect guinea-pigs from two rats which showed high reactions to OXA by means of mites, fleas, ticks or injections of emulsified brain and spleen tissue. Ticks and mites failed to transmit the OX19 virus but fleas (*N. simla*) fed on the same infected animals and injected into guinea-pigs produced orchitis and in rabbits agglutinins for OX19. Virus of the OXA type was isolated from fleas on rats during the time when the OXA type of fever was common but no OXA virus was recovered.

MEHTA (p. 358) found that in the Simla hills the flea population of rodents was lowest in the cold weather when the maximum number of murine typhus cases (OX19) occurs but fleas, lice and ticks are at a maximum in August to October when OXA cases occur. He suggests that larval mites and *Hyalomma* may transmit the rural (OXA) type.

YALON (p. 359) describes an outbreak of typhus-like fever with primary necrotic sore, enlarged glands and definite rash in the Punjab. The Weil-Felix reaction for *Proteus* OX19 was positive in 6 of 7 patients tested, but in low dilutions only.

HASSETT (p. 359) records a severe case in India, with symptoms of meningitis in which agglutinins for *Proteus* OX19 and OX2 were found in 1 in 1000 dilution.

Indeterminate type Vector tick

CUMMING (p. 779) shows that cases of typhus in the United States varied from 300 in 1931 to 1662 in 1936 and that increasing numbers are being reported from rural areas with new reservoirs found in mice, rats, marmots and squirrels.

CAREY and DUNCAN (p. 801) describe a case of Rocky Mountain fever in eastern U.S.A. There was high fever, a macular rash and agglutination of *Proteus* OX19. In the *Health News* New York (p. 801) it is reported that 4 further cases of Rocky Mountain fever have occurred in Long Island, all giving reactions to *Proteus* OX19.

An outbreak of spotted fever in Columbia is reported by PATINO *et al* (p. 361). Of 63 persons attacked 60 died. Blood from 7 patients produced fever in guinea-pigs and *Rickettsia* were found in cells in the peritoneal fluid and similar results were obtained by injecting emulsified

head lice from the patients though those from normal persons produced no reaction. Weil-Felix reactions with Proteus OX19 OX2 and OXK were all negative. In view of the evident house infection the authors suggest that a tick of the genus *Ornithodoros* may have been the vector.

PARKER (p. 800) shows that *D. variabilis* is the vector of Rocky Mountain fever in eastern U.S.A. and *D. andersoni* in the north western states. A mild type of the virus may be found in *H. leporis palustris* the common rabbit tick which does not bite man.

In Brazil, DIAS (p. 801) shows that though the dog is the principal reservoir host of spotted fever (including Rocky Mountain São Paulo and Minas Geraes types) the opossum and wild rabbit are also affected. The commonest tick vectors are *Amblyomma cajennense* and *A. striatum* and *R. sanguineus* may accidentally infect man as it is a common vector in dogs. TRAVASSOS (p. 365) believes that the opossum *Didelphis aurita* is a reservoir of São Paulo typhus. He succeeded in infecting several and found "typhus nodules" in the blood vessels of various organs though the animals were not ill. The virus could be passaged through the animals in series and was found in several opossums caught near São Paulo. The virus is transmissible by *Amblyomma cajennense* and in rabbits produces agglutinins for Proteus OX19. He (p. 797) obtained evidence of the transmission of the São Paulo virus in guinea pigs by various stages of *Amblyomma striatum*. He also (p. 798) found that these ticks collected from dogs were naturally infected and could transmit the disease by bite. *A. brasiliense* is also capable of transmitting the virus.

Rickettsia rickettsii has a characteristic morphology and multiplies in the cytoplasm of smooth muscle cells and of blood-vessel walls. It proliferates in the nuclei of cells in mammalian tissue culture. Non-pathogenic *Rickettsia* are found in ticks and PINKERTON and HASS (p. 372) investigating the differentiation found that the latter are not seen within the cell nuclei, nor are they pathogenic. They conclude from a large series of examinations that morphological appearances are not diagnostic and that the only unequivocal differentiation is the intranuclear occurrence of *R. rickettsii*. The non-pathogenic organisms are common in certain cells of the salivary glands of the ticks but do not produce massive invasion of the tissues generally as is the case with *R. rickettsii*.

TRAVASSOS (p. 786) maintains the virus of São Paulo typhus in white rats by injecting 1 or 2 cc. of normal guinea pig blood intra peritoneally 3 or 4 days after the rat is infected. He (p. 797) shows that the virus of São Paulo typhus multiplies in white rats though no lesions are found. The rats are strongly resistant to the virus and reduce its virulence on passage.

Although horses were apparently infected with living Mexican typhus virus, CASTANEDA and VARGAS-CURIEL (p. 797) failed to obtain a potent antiserum from them. They propose to super-immunize horses by intensive intravenous injections of formalized *Rickettsia*.

BLANC and BALTAZARD (p. 371) failed to infect a series of guinea pigs, monkeys and men, who had previously been inoculated with or had suffered from boutonneuse fever or had received living bile-treated vaccine with either the homologous virus or that of Rocky Mountain fever.

VIOLLE (p 789) shows that the viruses of boutonneuse fever and ship typhus cannot always be separated even by cross immunity tests and that the effects of inoculation in rabbits are similar. By ingestion pups can be infected with the endemic typhus virus and rats with the boutonneuse fever virus.

NOURI (p 364) has preserved the virus of boutonneuse fever by the inoculation of an emulsion of the swollen tunica suprarenal glands and spleen intraperitoneally into guineapigs repeating the subinoculations every 5 days. Reactions have remained uniform for more than one year with orchitis on the 3rd or 4th day and a rise of temperature immediately following this. Recovered guineapigs are immune to the virus of Rocky Mountain fever. The virus can also be preserved for some months by placing dead infected guineapigs in the ice chest.

LOGOTHETIS *et al* (p 790) show that virus from a patient with boutonneuse fever heated to 56°C for 30 minutes produced no reaction in the patient on intradermal injection but provoked a reaction in a normal person when mixed with the patient's serum. An emulsion of infected guineapig brain produced no results in animals but with normal serum gave a reaction. Ticks from the patient's house were infective.

Although blocking of the reticulo-endothelial system by colloids results in increase of severity of subsequently induced epidemic typhus in guineapigs NOURI (p 798) found that with endemic typhus and boutonneuse fever it resulted in unapparent infection with subsequent immunity.

OLMER and OLMER (p 788) record a case of boutonneuse fever occurring in Marseilles in winter which is unusual.

The development of a primary sore on the eyelid with involvement of the corresponding glands in a woman who in crushing a tick from a cat received a splash in her eye is recorded by AUBARET (p 367). A rash typical of boutonneuse fever developed.

BLANC *et al* (p 780) report two cases of typical boutonneuse fever contracted in West Africa from a tick infested dog brought from Marseilles.

In Senegal PELTIER *et al* (p 780) report a patient whose symptoms were those of boutonneuse fever with the exception that there was no *tache noire* and whose serum agglutinated *Proteus* OX19 1/500 and OX2 1/2000. (The reactions of two endemic typhus patients on the other hand were OX19 1/50 000 and OX2 1/200). Animals inoculated developed slight fever without orchitis and a pet dog belonging to the patient was infested with *Rhipicephalus* and had never been away from Senegal.

GERMAIN and MORVAN (p 782) report from Lorient a fever of the typhus group with rash and serum positive to *Proteus* OX2 and OY19 but without primary sore. Hitherto no case of boutonneuse fever has been reported from the Atlantic coast of France.

RAYBAUD (p 367) has observed that a *tache noire* typical of boutonneuse fever may occur with fever but without rash. He (p 789) reports a case of boutonneuse fever without rash but with primary sore.

GEAR and DOUTHWAITE (p 787) isolated a strain of tick typhus from a dog tick *Haemaphysalis leachi* in South Africa and conclude that this tick is the vector of that disease.

C Wilcocks

MALARIA.

PRECIS OF ABSTRACTS IN THIS SECTION

BOYD (p 808) reviews the present state of malaria prevention and control and concludes that for success control should not be a campaign but a long term programme utilizing measures of the highest degree of permanence.

SWEET (p 808) describes the three types of irrigation systems in Mysore State in relation to malaria. Minor irrigation from local tanks where water is scarce and therefore carefully conserved causes little malaria, large irrigation projects from greater tanks which seldom or never go dry are frequently malarious, while extensive river irrigation covering a large acreage with a perennial water supply is invariably highly malarious.

SCHWETZ (p 808) reports the finding of *P. ovale* and of schizonts of *P. falciparum* in native children suffering from afebrile endemic malaria in Central Africa, and SHIEBER (p. 809) the finding of *P. ovale* in a patient in Palestine.

GIGLIOLI (p 809) writing of malaria on the Coast Land of British Guiana, states that *A. darlingi* (not previously recognized there) is the main carrier of malaria in the Colony.

BOYD and MATTHEWS (p 809) report that, following natural inoculation with massive doses of sporozoites of *P. falciparum* parasites were first detectable microscopically in the blood of a negro patient on the 10th day and that in a series of individuals subinoculated daily with blood from this first patient, the seventh individual of the series was the first in whom parasites could be detected and in him the parasites were not found until the 8th day following subinoculation.

TOUMANOFF (p 810) discusses the possibility of malaria of buffaloes falsifying the oocyst and sporozoite indices of Anopheles in Indo-China.

SHUTE and LUGREANI (p 810) have investigated the longevity of races of *A. macdougalli* and from their observations are led to believe that the average *atroparvus* remains infective longer than the average *macdougalli*.

KITCHEN (p 811) examined the mature and immature erythrocytes in *P. falciparum* and *P. malariae* infections and found that *falciparum* appears to be indifferent to the age of the erythrocytes it invades, while *malariae* favours mature erythrocytes.

BOYD and KITCHEN (p 811) have examined the skin and subcutaneous tissue at the sites of infected mosquito bites. Their findings do not suggest that the lymph passages are the normal route by which the majority of sporozoites reach their destination.

MANCEAUX (p 812) has studied the leucocyte formula of acute malaria patients and notes that the changes in it are remarkably constant.

CRESTA (p 813) records his observations on 21 patients suffering from malaria with special reference to suprarenal function, and summarizes the literature on the subject. PIZZILLO (p. 813) reports on a patient in whom reactivation of malaria with pernicious symptoms was observed during intravenous adrenalin treatment. MARASOV (p. 814) discusses the literature of cases with symptoms of Addison's disease in which malaria appeared to be the aetiological factor.

PROSKE and WATSON (p 813) subscribing to the view that Henry's reaction is brought about by an increase in serum euglobulin have

therefore devised a protein-tyrosin reaction for the quantitative estimation of euglobulin as a diagnostic test for malaria

DURAND (p 814) reporting on the treatment with various sulphonamide derivatives of 36 patients suffering from either *vivax* or *falciparum* malaria concludes that the action of these drugs is not regularly effective enough for them to replace quinine or the usual antimalaria synthetic products though their antimalaria activity warrants further research on these lines COGGESHALL (p 824) has studied the therapeutic effect of sulphanilamide on *P knowlesi* infections in *rhesus* monkeys and concludes that this drug completely eradicates infection in the cases treated and that subsequent reinoculation reveals the existence of a residual immunity which may last for three months

LATASTE *et al* (p 815 816) describe a method for estimating quinacrine (the French equivalent of atebirin) in the blood. They have used this method to ascertain the repartition of quinacrine between red cells and plasma and the relationship between the blood concentration and urinary excretion of quinacrine

KIKUTH (p 816) discusses the chemotherapy of malaria on the basis of recent knowledge of the parasites

MOLLARET and SCHNEIDER (p 817) have studied the action of rhodoprequine on the schizonts of *P vivax*

DECOURT (p 818) discusses the principle on which antiplasmodial measures should be based.

CANET (p 818) elaborates the general conclusions drawn from a 4-years experience of mass prophylactic administration of quinacrine on the rubber plantations in the red-soil belt of Northern Cochinchina.

CLARK and KOMP (p 819) report on the 8th year's observations on malaria in Panama with the object of evolving a method of malaria control applicable to a native population of tropical America where antimosquito measures cannot be used.

HACKETT *et al* (p 820) write on the nature applicability and limitations of naturalistic measures of anopheline control the purpose of their report being to systematize existing knowledge.

MULLIGAN and AFRIDI (p 821) record the general principles which should be observed to obviate the creation of malarious conditions during engineering constructional works in India. JANDOLO (p 821) deals with bonification in respect of malaria in Italy

EATON (p 821) shows that a soluble malaria antigen occurs in the serum of monkeys with acute *P knowlesi* infection. This antigen when injected into normal monkeys gives rise to complement fixation antibodies similar to those produced by malaria infection but no protective or agglutinating antibodies are formed.

TUPA and CRUCA (p 822) have studied the histopathological lesions in experimental *P knowlesi* infections in *M rhesus* and conclude that this infection is associated with a hypertrophy of the reticulo-endothelial system in those organs where infective red corpuscles come into contact with the histiocytes

AFRIDI (p 823) has made observations on the extra-abdominal spleen (i.e. the spleen transplanted to the surface of the *pectoralis abdominalis* muscle and left lying between this and the skin) in monkeys infected with *P cynomolgi* and *P knowlesi*. In *cynomolgi* infection the chief enlargement of the spleen occurred after the parasites had reached their peak, while in *knowlesi* infection the maximum enlargement occurred before the height of the infection.

CIRCA *et al* (p. S23) have studied the mechanism of immunity acquired in intentional infections of general paralytics with *P. knowlesi*. It would seem that after recovery from the *P. knowlesi* infection there is a definite immunity independent of a premunition.

BOVD (Mark F) Malaria Retrospect and Prospect.—*Amer J Trop Med* 1939 Jan. Vol. 19 No. 1 pp. 1-6.

This is a presidential address. It is a brief review of the present state of malaria prevention and control. Except in the field of epidemiology the application of the discoveries of LAFERAN and ROSS has not yielded results commensurate with the importance of these discoveries or the importance of malaria. The reasons for this are discussed. "Malaria control should not be a campaign, it should be a long term program.

With the means at present available we will more economically utilize our resources, more quickly achieve our goal, and more firmly hold our position by the employment of the practices with the highest degree of permanency. We should build out malaria."

Norman White

SWEET (W. C.) Irrigation and Malaria.—Reprinted from *Proc. Nat Inst Sciences of India*. 1939. Vol. 4 No. 2 pp. 185-189

There are three types of irrigation in Mysore. Minor irrigation of small acreage from tanks the water supply being dependent on rainfall, is associated with little or no malaria. Water is scarce and treated with respect. Larger irrigation projects from large tanks which never go dry and which distribute water through a system of canals are frequently associated with malaria of some severity. Extensive river irrigations with perennial water supply distributed by large canals and many miles of subsidiary channels are invariably responsible for much malaria. Spleen indexes of children of areas representative of these three types of irrigation are produced. Figures are also produced illustrating the increased mortality following the inauguration of river water irrigation following the construction of the Cauvery Dam and the Irwin Canal. Water was as usual supplied in excess and no provision was made for drainage.

SCHWEITZ (J.) Sur quelques parasites rares trouvés dans le paludisme endémique des noirs de l'Afrique Centrale. (*Plasmodium orals* et schizontes de *P. falciparum*.) [Rare Parasites found in Endemic Malaria of Natives of Central Africa.]—*Rev. de Malariologia* Ser. I 1938 Vol. 17 No. 6. pp. 431-437

The author reports the finding of *P. orals* in the blood of several native children in the Congo suffering from afebrile endemic malaria. The presence of schizonts of *P. falciparum* in the peripheral blood is generally associated with very acute cases. The author reports their presence in the blood of children in East and West Congo who were not suffering from fever and who though heavily parasitized, were apparently well.

A. H.

SHIEBER (Chaim) The Presence of *Plasmodium ovale* in Palestine.—*Harefuah* Jerusalem, 1939 Apr Vol. 16 No 4 (94) [In Hebrew pp 122-125 [11 refs.] English summary p II]

A mixed infection of *Pl vivax* and *Pl ovale* was found in a patient living near Haifa.

The *Pl ovale* was typical in every respect and showed all the characters mentioned by Stephens in his original description.

This is the first record of *Pl ovale* acquired in Palestine

GIGLIOLI (George) Malaria on the Coast-Land of British Guiana.—*Health Conditions on the British Guiana Sugar Estates* 1938 Nov 21 Appendix I and II pp. i-xxvi.

Three species of Anopheles are prevalent on the coast of British Guiana *tarsimaculatus albistarsis* and *darlingi*. Till recently the two latter species have been classified as a single species erroneously identified as *argyritarsis* which apparently is not found on the coast. Of 13 000 Anopheles captured in houses 88 per cent were *darlingi*, of 2 000 captured in stables only 2.6 per cent. were *darlingi*. Both *tarsimaculatus* and *albistarsis* are zoophilic whereas *darlingi* has a predilection for man. These and other considerations lead to the conclusion that *A. darlingi* is the only important vector. It breeds in bodies of water of considerable size the water must have a low saline content and a neutral or very slightly acid reaction. Its breeding places are protected by vegetation affording shelter for the adult and some shade for the larva. It is a strict night flier its dispersion and range of flight are favoured by high atmospheric humidity.

Between August and November 1937 5 814 children under 12 years of age were examined on 15 estates. Spleen rates from zero to 60 per cent were observed the parasite rates ranged from 13.5 to 68.7 per cent. There was epidemic prevalence of malaria when the survey was made. In the positive films unidentified large ring forms were found in 42.8 per cent *P. vivax* in 28.8 *P. falciparum* in 7.3 and *P. malariae* in 21.1 per cent.

Splenic enlargement is much more marked and persistent among East Indians than among negroes living under exactly similar conditions.

The incidence of malaria diminishes from west to east along the coast as does atmospheric humidity. The distribution of malaria and of *A. darlingi* are coextensive.

Epidemic conditions of 1937 and 1938 were in large part determined by excessive rainfall, which markedly increased breeding facilities for *A. darlingi* and provided the high atmospheric humidity favourable to this species.

N IV

BOYD (Mark F) & MATTHEWS (Choice B) An Observation on the Incubation Period of *Plasmodium falciparum*—*Amer J Trop Med* 1939 Jan. Vol. 19 No 1 pp 69-71

A male negro patient for whom malaria therapy had been prescribed had 30 anophelines applied to him 25 fed. Of these 25 sporozoites were found subsequently in the salivary gland of 21. Thereafter 10 cc. of his blood was inoculated daily into one of a series of other susceptible patients until the 10th day when parasites were found in the blood and a clinical attack commenced. The seventh individual

of the series was the first in whom parasites could be detected in hum parasites were found on the 8th day following subinoculation and fever commenced on the 9th day. Very similar results have previously been reported by the first named author in the case of *P. vivax* (see this *Bulletin* 1935 Vol. 32, p. 405) N IV

TOUMANOFF (C) Le paludisme des buffles peut-il fausser les indices oocystiques et sporozoïtiques en Indochine? (Can Malaria of Buffaloes falsify Oocyst and Sporozoite Indices in Indo-China?)—*Bull Soc Path. Exot.* 1939 Jan. 11 Vol. 32. No 1 pp 80-87 [11 refs.]

The author previously reported the persistence of malaria sporozoites in two *A. minimus* after the insects had fed several times on cattle [see this *Bulletin* 1938 Vol. 35 p. 569]. In referring to that report BRUMPT put forward the hypothesis that the malaria of buffaloes might conceivably falsify the oocyst and sporozoite indices of anopheline vectors in Indo-China. The present paper rebuts that hypothesis. *P. budalis* has never yet been found in Indo-China. The evolution of malaria parasites in the malaria vectors of Indo-China (*minimus jayponensis* and *hyrcanus*) is sometimes slower than is generally thought. It is consequently not very easy to determine the age of sporocysts from their morphological appearance. This tardy evolution is sometimes noted at high temperatures which are considered to be optimal. The persistence of sporozoites in the two cases reported was connected with active sporocystic evolution in insects heavily infected on several occasions. It is possible that the specially slow evolution may be related to the absorption of animal blood by the infected insect, but this remains to be proved. N IV

LEESON (H. S.) Keys to the Known Larvae and Adults of West African Anopheline Mosquitoes.—*Bull Entom Res* 1939 Apr Vol 30 Pt 1 pp 129-161 With 36 figs

SHUTE (P. G.) & UNGUREANU (E.) Preliminary Report on the Longevity of the Races of *Anopheles maculipennis*—League of Nations Health Organisation, Malaria Commission Geneva 1939 Feb. 21 C.H./Malaria/273 11 mimeographed pp

The authors study the proportion of mosquitoes (races of *A. maculipennis*) which survive under various experimental conditions and the proportion which might develop a salivary infection with *Plasmodium*

It has been repeatedly found that *A. maculipennis atroparvus* lives well in captivity and that about 80 per cent of a batch will survive long enough to show sporozoites in salivary glands. The races *typicus* and *mesicus* give a high mortality in captivity

In the simplest experiment here described twenty specimens of each of four races of *A. maculipennis* were kept at 24°C and a relative humidity of 70-80 per cent. On the 11th day (the day on which sporozoites of *P. vivax* appeared in glands of *atroparvus*) 19 *atroparvus*, 14 *labrarchiae*, 14 *typicus* and 10 *mesicus* were alive. Six other experiments were carried out, under varying conditions of temperature and humidity, all but one in summer in Rumania. The proportion of *atroparvus* living long enough to become infective was consistently 85-100 per cent, the proportion of other races surviving long enough

was much lower (only 32 per cent in *messeae*) but inconsistently so. The different races are not strictly comparable for all *atroparvus* were fertilized and laying eggs but the others were not fertilized (and had therefore presumably a lower metabolic rate).

In one experiment bred females of *atroparvus* and *messeae* were fed on the same human patient. The results were —

	<i>atroparvus</i>	<i>messeae</i>
Number of females fed	28	28
Positive sporozoites	22	17
Mean number of oocysts	61	15

The authors believe that the average *atroparvus* would have continued to be infective for a longer time than the average *messeae*.

CRAWFORD (R.) Some Anopheline Pupae of Malaya with a Note on Pupal Structure.—110 pp With 27 figs. Published by the Govt of the Straits Settlements and the Malaria Advisory Board F.M.S. 1938. Singapore Govt Printer

KITCHEN (S. F.) The Infection of Mature and Immature Erythrocytes by *Plasmodium falciparum* and *Plasmodium malariae*.—*Amer J Trop Med* 1939 Jan Vol 19 No 1 pp 47-62 With 5 figs [10 refs]

The author has previously reported the marked partiality of *P. vivax* for reticulocytes [see this *Bulletin* 1939 Vol 36 p 138]. He now publishes the results of similar observations using the same technique of three patients suffering from typical clinical attacks of *falciparum* malaria and of two patients with *malariae* infections. All were cases of induced malaria, two of the *falciparum* cases being infected by anophelines, the other and the two *malariae* cases by blood inoculation. The results are clearly set out in tables and graphs. The total numbers of mature red cells infected with *P. falciparum* constantly exceeded the total numbers of reticulocytes so infected. The two types of cell alternated irregularly in showing the higher percentage of infection. The stage of the disease did not appear to influence these variations. The incidence of infection of reticulocytes with *P. malariae* was very low; this parasite was absolutely and relatively much more frequent in mature erythrocytes.

N. W.

BOYD (Mark F.) & KITCHEN (S. F.) The Demonstration of Sporozoites in Human Tissues.—*Amer J Trop Med* 1939 Jan Vol 19 No 1 pp 27-31 With 4 figs on 2 plates

The skin and subcutaneous tissue about the site where a single infective mosquito was applied was removed under local anaesthesia as soon as possible after the removal of the mosquito. The tissue was sectioned and searched for sporozoites. Three cases are reported. In no case did excision prevent infection. In one case two typical unchanged sporozoites were seen in one section about 3 mm. from the

surface of the skin they were extravascular and surrounded with extravasated blood.

In four other cases the site of mosquito inoculation was the inguinal region one or two of the larger adjacent lymph nodes were excised the day following the application of the mosquitoes. Sections of the glands were examined. In one case several sporozoites were observed, all in connective tissue none in lymphoid tissue. In no case did the removal of glands have any effect on the subsequent infection. The appearance of the sporozoites found in lymph nodes was unaltered indicating that they had neither reached their destination nor achieved their destiny. The finding does not suggest that the lymph passages are the route by which the majority of sporozoites travel to their destination.

MASCEAUX (A.) La formule leucocytaire dans le paludisme aigu. [Leucocyte Formula in Acute Malaria.]—*Bull Soc Path Exot* 1939 Feb. 8. Vol. 32 No. 2 pp. 150-151.

The author has made a study of the leucocyte formula of a large number of patients suffering from acute malaria. Changes in it are remarkably constant and correspond to the reaction of the organism to the infection. During the five days following the application of infected anophelines there is an increase of monocytes with the appearance of Turk cells and Rider cells. During the attack there is an initial leucocytosis, with increase of neutrophilic cells and mononuclears; this diminishes during the attack and is replaced by mononuclear increase alone after the attack. After several days, or several attacks, the initial moderate leucocytosis is sometimes replaced by slight leucopenia. polynuclear neutrophils diminish commonly to 40 to 50 per cent. polynuclear eosinophils commonly disappear. monocytes oscillate round 10 per cent. and lymphocytes frequently amount to 40 to 50 per cent. With recovery the formula gradually returns to normal, but monocytosis may persist. This persistence indicates a still active reticulo-endothelial system. A return of the formula to normal is a good test of clinical recovery.

These changes in the leucocyte formula follow the fluctuations of the serological index (melano-flocculation). Blood cholesterol falls and rises with the number of polynuclear cells. The bilirubin in the blood is increased, the increase tending to disappear when symptoms disappear but increased blood bilirubin like excess monocytes and for similar reasons may persist. The return to normal level of bilirubin and monocytes is evidence of complete cure.

A II

CHESSA (Fausto) La funzionalità surrenale nella malaria. [Function of the Suprarenals in Malaria]—*Riv di Malarologia* Sez. I 1938. Vol. 17 No. 6 pp 439-455 [48 refs] French summary (5 lines)

An interesting summary of the literature of the subject is followed by notes of 21 patients suffering from malaria, both acute and chronic including both *vivax* and *falciparum* infections with special reference to suprarenal function. They each received an intravenous injection of insulin. Eight cases exhibited a hypersensitivity to insulin i.e. cases in which the fall in glycaemia following the injection exceeded 0.30 mgm. the glycaemia remaining below the pre-injection level for two hours. PROSKE (H. O.) & WATSON (Robert B.) The Protein Tyrosin Reaction. A Biochemical Diagnostic Test for Malaria—*Public Health Rep* 1939 Feb 3 Vol. 54 No. 5 pp 158-172. [40 refs.]

This paper opens with a survey of the literature of Henry's Reaction. The authors subscribe to the generally accepted opinion that that reaction is due to a disequilibrium of the serum proteins characterized by an increase of the euglobulin fraction which flocculates upon dilution with distilled water or with weak salt solutions. If this be so the quantitative chemical estimation of the euglobulins should give results similar to those of Henry's Reaction. A method has been devised for such an estimation. This is described in detail.

A 14 per cent. solution of anhydrous sodium sulphate in distilled water is used to precipitate the euglobulins. Euglobulin like other proteins has chromogenic properties in the presence of a phenol reagent. The colour produced by the euglobulin in the sample is compared with that produced by standard solution of pure tyrosin (Pfanstuehl). The phenol reagent used is that of Folin and Ciocalteu. All glassware should be chemically clean. The serum pipettes should have fine tips and the serum should be clear.

As a result of the examination of over 2,000 normal blood sera, the authors have found that the tyrosin index for euglobulin fluctuates between 50 and 80. For serum of malaria patients the index ranges from 80 to 280 or higher. The test was found to be indicative of malaria in 97.4 per cent. of known malaria cases compared with 81.9 per cent. positive thick blood films examined at the same time. The test is of course no more specific than is Henry's Reaction but it is very sensitive in malaria. The test is moreover relatively simple and needs no expensive apparatus such as a photometer. PIZZILLO (Giuseppe) Sulla cura adrenalinica venosa nelle infezioni malariche. Nota XIII—Sindrome pernicioza da riattivazione [Reactivation of Malaria, with Pernicious Symptoms, during Intravenous Adrenalin Treatment.]—*Riv di Malarologia* Sez. I 1938 Vol. 17 No. 6 pp 456-461. With 1 chart. German summary (3 lines)

A man aged 30 suffered from an acute attack of *falciparum* malaria in Italian East Africa. He was repatriated and suffered from a relapse during the voyage home. He was admitted to hospital again suffering from fever a month after his arrival in Italy. He was kept four days under observation without treatment. He had quotidian fever.

there were numerous *falciparum* parasites in his blood. On the 5th day adrenalin treatment was begun the initial dose being 1/50 mgm., associated with quinine by mouth 1.20 gm. a day. On the second day of treatment the temperature fell to normal and the quinine was suspended. After the 15th daily injection of adrenalin 1/10 mgm. fever returned and quinine was given. The fever was quotidian. During the third paroxysm the symptoms became grave, temperature 40.2 blood-stained bilious vomiting delirium, diffuse abdominal pain small frequent pulse, 160 and rapid superficial respiration. Quinine was given and the condition improved. The following day the adrenalin injection was followed by a return of the grave symptoms with diarrhoea. A second injection of adrenalin was given on that day and 0.5 gm. of quinine intramuscularly. Improvement followed. Injections of adrenalin 1/10 mgm. were given twice daily and one gram of quinine intramuscularly during the six days that the fever lasted. Thereafter adrenalin injections were given once a day till the end of the course of treatment. The patient made a complete recovery.

The appearance of pernicious symptoms for the first time during a relapse three months after the primary attack in which grave symptoms did not appear is of interest as is also the apparent efficiency of adrenalin in relatively large doses, in combating pernicious symptoms.

MARASOV (G.) A doença de Addison de origem palúdica. [Addison's Disease of Malarial Origin. — *Brasil Medico* 1939 Jan. Vol. 53 No 5 pp 83-85 [20 refs.]

A discussion of the literature of cases with symptoms of Addison's Disease in which malaria infection appeared to be the aetiological factor is followed by a description of two illustrative cases. They occurred in Spain both were *P. vivax* infections. The author concludes that the malaria parasite can produce symptoms of suprarenal insufficiency and that in individuals with a constitutional predisposition this acute insufficiency can develop into a chronic condition that is to say Addison's Disease. Such may occur in severe tropical infections as well as in benign tertian infections of Western Europe.

SIEGEBEEK VAN HEUKELOM (A.) De behandeling van acute malaria kinine of atebine? [The Treatment of Acute Malaria. Quinine or Atebina?] — *Nederl Tijdschr v Geneesk* 1939 Apr 1 Vol. 83 No 15 pp 1447-1455

1. DURAND (Paul) Action des dérivés sulfamidés et sulfonés sur l'hématozoaire du paludisme. [Action of Sulphonamide Derivatives on the Malaria Parasite.] — *Arch Inst Pasteur de Tunis* 1939 Mar Vol. 28 No. 1 pp 82-83

2. — Action des dérivés sulfamidés et sulfonés sur l'hématozoaire du paludisme — *Bull Soc Path. Exot* 1939 Mar 8 Vol. 32 No 3 pp 283-290.

1. This is a report on the treatment of 36 patients suffering from either *vivax* or *falciparum* malaria with various sulphonamide derivatives. The infections were in no case recent the patients were suffering from relapses. The derivatives used were rubiazol (prontosil) septasine

soluseptasine rodilone and septoplux (sulphanilamide) All of these preparations were ineffective in certain cases In many cases fever was suppressed sufficiently rapidly but relapses were not rare, sometimes these occurred before the end of treatment In half the cases action on schizonts was observed Gametes especially crescents were more resistant In two ~~very~~ cases treated with rodilone gametes disappeared while schizonts persisted The author concludes that the action of these drugs is not regularly effective enough for them to replace quinine or the usual antimalaria synthetic products in the treatment of malaria but the fact that they do at times possess antimalaria activity warrants a continuation of such observations more especially if new derivatives should be produced

ii This appears to be a very similar account of the same cases

LATASTE (C) NGUYEN VAN LIEN & FARINAUD (M E) Recherche et dosage de la quinacrine dans le sang [Determination and Estimation of Quinacrine in the Blood.]—*C R Soc Biol* 1939 Vol 130 No 5 pp 422-424

The methods of Chopra and Roy and of Hecht did not permit the estimation of the very small amounts of quinacrine generally present in the blood of patients undergoing curative or preventive treatment. The authors' method is as follows A large quantity of blood 25 cc. is taken and an anticoagulant liqueur (sodium polyanethol sulphate see this *Bulletin* 1938 Vol 35 p 704 and *Bulletin of Hygiene* 1938 Vol 13 p. 663) 0.20 gm per litre of blood added. The blood is centrifuged for a considerable time in a tube graduated in tenths of a cc. The volume of the cells can be read directly.

To the sample to be examined is added an equal quantity of 60 per cent pure potash rapidly liquefied in a water bath at 100 C. The first extraction is done with Hecht's solvent pure benzene free from thiophene 8 parts amyl alcohol 2 parts This takes up the blood pigments and the acridine. Prolonged shaking is followed by centrifuging. The solvent is pipetted off. The process is repeated, the washings being added to the solvent.

The total benzo-amylic extract is then treated with $\frac{1}{10}$ hydrochloric acid first with 3 cc then 2 cc and finally 1 cc decanting each time the aqueous solutions which are collected in a colourless tube of 10 to 12 mm diameter. The blood pigments remain in the benzo-amylic fraction. After alkalinization the acridine is collected in a thin layer of amyl alcohol. This extract contains the whole of the quinacrine in the sample. It is compared in diffused light with standard dilutions of the drug similarly treated ranging from 0 to 50 γ by 2.5 γ gradations ($\gamma = 0.001$ mgm). By this method quantities as small as $\frac{1}{10}$ mgm of quinacrine per litre of blood can be estimated with an error not exceeding 10 to 15 per cent. [See also this *Bulletin* 1938, Vol 35 p 569.]

LATASTE (C) FARINAUD (M E) & NGUYEN VAN LIEN La répartition erythroplasmatique de la quinacrine [The Repartition of Quinacrine between Red Cells and Plasma.]—*C R Soc Biol* 1939 Vol 130 No 6. pp 522-525

Can an elective affinity of quinacrine for red cells explain the schizonticidal action of that drug? To answer this question the

authors, employing their method described above examined a patient under treatment with quinacrine for two periods of five days each, with an interval of two weeks 0.3 gm. a day. The first definite appearance of the drug in the blood occurred after a delay which may extend to 2 or 3 days from the beginning of treatment. The maximum concentration was found on the day following the administration of the last dose. The drug disappeared from the blood 5 or 6 days after the end of treatment. The total amount of quinacrine in the blood was but a fraction of the amount ingested, about 4 per cent. The drug had a very definite affinity for red cells the amount of quinacrine recovered from red cells was three times greater than the amount recovered from the same volume of plasma. The fixation of quinacrine by red cells is not a vital phenomenon it can be demonstrated *in vitro*. There is a relationship between the quantity of protein and the concentration of quinacrine. \ W

FARDAUD (E.) LATASSE (C.) BACCIALOZE (L.) & CANET (J.)
Rapports entre la concentration sanguine et l'élimination urinaire de la quinacrine [Relationship between Blood Concentration and Urinary Excretion of Quinacrine.]—*C. R. Soc. Biol.* 1939 Vol. 130. No. 7 pp. 623-624

The maximum concentration of quinacrine in the blood of Annamite patients treated with 0.30 gm. a day for 5 days varies between 0.60 and 1.50 mgm. per litre. In two patients the relationship between this concentration and the urinary excretion of the drug was studied. The urinary excretion reaches its maximum the day the last dose is taken small quantities can be detected in the urine for a considerable time thereafter. If the treatment be then repeated the urinary elimination of the drug increases immediately after the first dose indicating an accumulation of the drug in the organs. In one patient whose daily excretion of urine was 1,000 cc. the maximum daily elimination of quinacrine was 18 mgm. after a latent period of several days and thereafter he continued to excrete 9 to 10 mgm. a day till the treatment was repeated. The second patient excreted from 1,500 to 2,000 cc. of urine a day he began to excrete the drug after a shorter latent period the maximum amount being 34 mgm. in 24 hours and the residual elimination was at a rate of 5 mgm. a day. The maximum concentration of the drug in the blood for any given individual remains constant whatever the number and frequency of treatment. The saturation of the tissues that have accumulated the drug resulting from a repetition of treatment, is evidenced by a sudden increase in the amount eliminated in the urine but not by any increase of the blood concentration of the drug above the maximum previously noted. \ W

HILFTH (Walter) Die Chemotherapie der Malaria auf Grund neuer parasitologischer Erkenntnisse [The Chemotherapy of Malaria on the Basis of Recent Knowledge of the Parasites.]—*Wienck Med. Wch.* 1939 Mar 10. Vol 89 No 10. pp 382-385.

Besides measures against mosquitoes attempts have been made to interrupt the developmental cycle of malaria parasites in man and mosquitoes by means of drug. Quinine and atabrin are effective clinically while plasmoquine act against the sexual forms in malignant

tertian malaria and prevents the fusion of male with female gametocytes and also appears to be more efficient in preventing relapses.

Recently Certuna was introduced and is well tolerated besides it does not give rise to methaemoglobin formation or secondary symptoms. It can prevent the exflagellation of male gametocytes and is active against the gametocytes of malignant and benign tertian parasites. It possesses the novel property when given in minimal doses of arresting the development of the fertilized female at the oöcyst stage. It has no prophylactic action in induced human malaria.

So far no causal prophylactic is known. A stage in development between sporozoites and intracellular forms has been suggested to explain long incubation periods and the inactivity of drugs in general as well as relapses. In the case of paralytics inoculated with blood a small dose of drug on the other hand, gives rise to cure as the intermediate stage of the parasite is here probably absent.

The first positive discovery of the possible intermediate stage was made with *P. elongatum*. Later with the same parasite pigmentless forms were demonstrated in endothelial cells and subsequently for *P. gallinaceum* and *P. cathemerium*. The author considers that these unpigmented forms are part of the developmental cycle of the parasite. As with sporozoites these forms are not affected by known drugs in the same way as intracellular forms but plasmoquine may be an exceptional drug as the author's researches indicate.

Endothelial forms have been noted in the bone marrow of an African monkey and reported likewise for malignant and benign tertian malaria in man following sternal puncture at the end of the incubation period subsequent to sporozoite infection. The forms are similar to those found in bird malaria. The verification of these findings will help to clarify some nebulous points in the epidemiology of malaria and assist in further chemotherapeutical progress. J. D. Fulton

MOLLARET (P) & SCHNEIDER (J) Contribution à l'étude de la paludothérapie action d'un médicament gaméticide dans le paludisme thérapeutique [Contribution to the Study of the Anti Malarial Activity of a Gametocide in Malaria Therapy]—*Bull. Soc. Path. Exot.* 1939 Feb 8 Vol. 32 No 2 pp 207-221 With 8 figs

This concerns the action of rhodoprequine 0.03 gm a day for 3 days on the schizonts of *P. vivax*. The interesting observations recorded were all made on patients undergoing malaria therapy. The strain of *P. vivax* used has special characteristics. It has been transferred direct from patient to patient for ten years and has assumed the attributes of a fixed virus. Its incubation period has been reduced to 7 days—this period is not further reduced by intravenous injection. It is generally administered subcutaneously or intramuscularly. The interval between attacks of fever has been reduced from 48 to 42 hours. The febrile reaction is intense. The parasite density in the blood is small. The strain is extremely sensitive to quinine.

The authors have shown that rhodoprequine in the doses mentioned above in addition to its recognized gametocidal action, has a certain action on the schizonts of this strain. Its administration is followed, after a delayed final attack by a cessation of fever and the disappearance from the blood of both gametocytes and schizonts. If

authors, employing their method described above examined a patient under treatment with quinacrine for two periods of five days each with an interval of two weeks, 0.3 gm. a day. The first definite appearance of the drug in the blood occurred after a delay which may extend to 2 or 3 days from the beginning of treatment. MOLLARET (P) & SCHNEIDER (J) Contribution à l'étude de la paludothérapie action d'un médicament gaméticide dans le paludisme thérapeutique [Contribution to the Study of the Anti-Malarial Activity of a Gametocide in Malaria Therapy]—*Bull Soc Path Exot* 1939 Feb 8 Vol 32 No 2. pp 207-221 With 8 figs

This concerns the action of rhodoprequine, 0.03 gm. a day for 3 days on the schizonts of *P. vivax*. The interesting observations recorded were all made on patients undergoing malaria therapy. The strain of *P. vivax* used has special characteristics. It has been transferred direct from patient to patient for ten years and has assumed the attributes of a fixed virus. Its incubation period has been reduced to 7 days—this period is not further reduced by intravenous injection. It is generally administered subcutaneously or intramuscularly. The interval between attacks of fever has been reduced from 48 to 42 hours. The febrile reaction is intense. The parasite density in the blood is small. The strain is extremely sensitive to quinine.

The authors have shown that rhodoprequine in the doses mentioned above in addition to its recognized gametocide action has a certain action on the schizonts of this strain. Its administration is followed, after a delayed final attack by a cessation of fever and the disappearance from the blood of both gametocytes and schizonts. If

subsequently an auto-haemo-injection be given attacks of fever recommence and parasites reappear in the blood after an interval of from four hours to four days. These reappeared parasites are well developed forms the schizonts show no tendency to segment or to leave the red cell (Decourt's dysgonic action). If blood containing such forms be inoculated into another subject the schizogonic capacity of the parasites is regained. The inhibition of schizogony determined by rhodoprequine does not prevent the further development of gametes. \ 17

DECOURT (Ph) La lutte antiparasitaire. Son application dans la pratique. [Anti-Malaria Measures their Practical Application.] —*Bull. Soc. Path. Exot.* 1939 Jan. 11 Vol. 32 No 1 pp. 69-80.

Malaria prevailing in such varying conditions it is impossible to establish a standard method of antiparasitic activity that is generally applicable. With this fact in mind, the author proceeds to discuss the principles on which successful measures should be based. A study of the local problem is the first essential, parasitology and morbidity, anophelism and human geography. Splenic, splenometric and parasite indexes should not be confined to the child population adults should receive similar attention. The incidence of febrile attacks, mortality, still births, and the effects of morbidity on the social and economic life of the community all call for study. Serometric indices give valuable information as to the immunity of the community.

Collective prophylaxis with synthetic drugs involves the use of quinine and rhodoprequine or the association of the two, prenaline of these quinine is fundamental. A fixed daily dose of quinine should be used, the rhythm of administration varying with circumstances. Thus it may be advisable to administer the drug three times the first week, then weekly and subsequently increasing the intervals to ten days and finally twice monthly. If a large proportion of the population are submitted to treatment and if there is not free communication with other malarial communities that are not being treated, there are great advantages in associating a gametocide with quinine the administration of the drugs can be spaced out to a greater degree and more quickly than if quinine be used alone. If antiparasitic measures are applied on a sufficiently large scale administration of drugs twice a month should be considered the normal rhythm. Examples are given of very varied conditions that called for equally varying treatment. \ 17

CASSET (J) Note sur les résultats obtenus au cours de quatre années de prophylaxie collective antipaludique par médicaments synthétiques sur les plantations des Terres Rouges (Nord Cochinchine). Results of Four Years Mass Prophylaxis with Synthetic Drugs in Plantations in North Cochinchina. —*Bull. Soc. Path. Exot.* 1939 Jan. 11 Vol. 32 No 1 pp. 58-60.

This paper elaborates the general conclusions derived from four years experience of the prophylactic administration of quinine in the rubber plantations in the red-soil belt of northern Cochinchina, where malaria is persistently hyperendemic. The severity of the malaria is directly conditioned by the presence and prevalence of

A. minimus this is very little subject to seasonal variations. From the end of March to the middle of June and again in October and November there is some mitigation of the severity of the disease but only in the former period is the improvement sufficiently well marked to allow of temporary suspension or diminution of drug prophylaxis. It is recognized that in a hyperendemic region such as this the administration of drugs should never be regarded as the sole method of permanent prophylaxis excellent though the temporary results may be. Antilarval measures and improvement of the social life should go hand in hand with drug administration the latter being only an adjuvant.

The populations treated are subject to discipline and control an essential condition for successful drug prophylaxis. The drug was taken in the presence of the doctor or of another European. Many thousands of coolies have been treated with quinacrine but no untoward results have been noted. Discolouration of the skin has been exceptional and there has been no repugnance towards the drug such as was commonly evidenced to quinine. Synthetic remedies are undoubtedly more effective than quinine. A serious outbreak can be suppressed almost immediately by the administration to a village population of quinacrine 0.30 gm a day adult dose for three or five days examples are given. The working capacity of a labour force can thus be quickly regained but after a few weeks conditions relapse to their former severity in the absence of a follow-up treatment. For such continuous treatment the daily dose used was the same 0.30 gm. The frequency of the distribution varied with local conditions the chief of which is the degree of prevalence of *A. minimus*. Any standard treatment is a heresy. In general administration once a week was found necessary and sufficient. The arrival of heavily infected contingents of labourers a cold spell specially arduous labour or other adverse conditions sometimes necessitate more frequent administration every five days or even every three days. Experience has not shown that the association of a gametocide with quinacrine, in collective prophylaxis in such hyperendemic areas serves any useful social or economic purpose. N II

CLARK (H C) & KOMP (W H W) An Eighth Year's Observations on Malaria in Panama.—*Amer J Trop Med* 1939 Jan. Vol. 19 No 1 pp 33-46

As explained in previous reports of this series the main object of these studies is to evolve a method of malaria control applicable to a native population of tropical America where antimosquito measures cannot be used. Early attempts at eradicating the seed bed of infection gametocytes in young children and adolescents with drugs at present available had failed. Not all carriers of infection can be reached, and in a large number of cases no drug or combination of drugs can eradicate infection. The treatment of sub-clinical cases may destroy a certain amount of immunity. Drug control methods failed to control the cyclical epidemic of malaria that occurred in Panama in 1935. The present progress report contains nothing to modify these conclusions. In the year under review 1937-38 one group was treated with atebryn 0.1 gm. thrice daily for 5 days followed by plasmoquine 0.01 gm. twice daily for five days. Another group was treated with quinine sulphate 15 grains daily for 5 days followed by

plasmogquine 0.01 gm. twice a day for five days. The treatment was given to all parasite carriers discovered at monthly surveys. Both methods appeared to be equally effective. The parasite rates were the lowest yet recorded—a normal decline and treatment both contributed to this. Of individuals examined in all twelve-monthly surveys, 36.8 per cent had parasites in their blood as compared with 43.5 in 1936-37. *P. falciparum* was found in 75 per cent of the positive films. Only one infant under one year of age out of 53 examined was found infected. The method adopted has almost abolished clinical illness from malaria but the disease has not been eradicated. A rise in clinical malaria and in the general infection rate is expected when the overdue peak of the malaria curve occurs. In Panama transmission can occur throughout the year. Parasite rates are not related to rainfall.

HACKETT (L. W.) RUSSELL (P. F.) SCHARFF (J. W.) & WHITE (R. Senior). The Present Use of Naturalistic Measures in the Control of Malaria.—*Bull. Health Organisation (League of Nations)* 1938 Dec Vol 7 No 6. pp 1016-1064. With 13 figs. 42 refs.]

In this useful report the authors consider the nature, applicability and limitations of 'naturalistic' methods of anopheline control and the results obtained thereby in many lands. Naturalistic measures are defined as deliberate extensions or intensifications of those natural processes which tend to limit the production of mosquitoes or their contact with man. These measures are classified as chemical, physical and biological. The chemical measures against aquatic stages of the mosquito are pollution of water and changing salt content of water. The physical measures are natural fills, warping, silting, sluicing, flooding, fluctuating water level, intermittent drying, agitating, stagnating (ponding) or setting water in motion, mudding, shading or clearing, and drying by planting. The biological measures are natural enemies (predators), changing flora and fauna, and off-season attack. In addition naturalistic measures against adult mosquitoes are referred to: chemical, creating repellent barriers of odorous plants, and administering drugs like sulphur which cause odorous perspiration; physical, destruction of shelters, clearing, creation of plant barriers to flight, and rendering bedrooms or dwellings unattractive as resting places; biological, introduction of natural enemies, deviation by animals, and winter killing. Of these naturalistic measures against adult mosquitoes only animal deviation needs serious consideration.

No new facts are reported, the purpose of the paper being to systematize existing knowledge. In doing this the authors have rendered useful service. Many of these measures are important because of their potential adaptability to rural areas where other methods of mosquito control have been impossible. Further progress requires increased knowledge of mosquito ecology: this calls for co-operation of medical, malarialogist, biologist, chemist, engineer and agronomist. Rural malaria is closely connected with agriculture and pisciculture. Measures that have already achieved success in certain areas and have possibilities of more general application include herbage packing, sluicing, shading, and the use of exotic fish like *Gambusia*. Some naturalistic methods offer the advantage of a combined attack on more

than one vulnerable point in the biology of the larva. Herbage cover pollutes water shades it and may obstruct egg laying mechanically. salinification may destroy larval food as well as larvae shading may limit egg laying or larval growth or inhibit sheltering algae. Photographs illustrating successful application of some of these methods add interest to the paper

MULLIGAN (H W) & AFRIDI (M K) The Prevention of Malaria Incidental to Engineering Construction—*Health Bull No 25 Malaria Bureau No 12* pp 11-52 With 8 photos on 4 plates & 11 figs. (6 folding) 1938 Delhi Manager of Publications. [7 annas or 8d]

The object of this Bulletin is to record in simple language the general principles which should be observed during construction works of various kinds so as to obviate the creation of conditions which will subsequently produce mosquitoes and malaria." These opening words of the pamphlet adequately describe its scope. It is well done. There is obviously no scope for originality in the compilation of a work of this kind but had the precautions which are clearly outlined been taken in the past the benefits conferred by engineering achievement would not have had to be offset by increased prevalence of malaria. Works of this kind should lessen the probability of future neglect in this important matter

EATON (Monroe D) The Soluble Malarial Antigen in the Serum of Monkeys Infected with *Plasmodium knowlesi*—*Jl Experim. Med* 1939 Apr 1 Vol. 69 No 4 pp 517-532. With 3 figs. [10 refs]

It has been shown that the serum of monkeys suffering from severe acute *Plasmodium knowlesi* infections contains a soluble antigen which in the presence of immune serum from hyper immunized monkeys gives a strong complement fixation reaction. The titre of the antigen is related to the extent of the infection during its acute phase. Intra venous injection of the serum containing the antigen into monkeys causes the production of specific complement fixing antibodies which

react with the serum antigen as well as with an antigen extracted from parasitized cells. As monkeys immunized with the serum antigen were in no way immune to infection there exists the possibility that the serum antigen was the product of the destruction of red cells. As the sera of certain monkeys and human beings infected with *P. knowlesi* give little reaction with the serum antigen and a stronger one with antigen prepared from parasitized cells it would appear that another complement fixing antigen is present in these cells. This soluble serum antigen is not excreted in the urine is labile to acids and alkalis resists a temperature of 56°C and is precipitated for the most part in the albumin fraction by ammonium sulphate.

C. M. WENYON

TUPI (A) & CIUCA (M) with the collaboration of G. RADENSKI & P. IOVASCU Contribution à l'étude des lésions histopathologiques dans l'infection expérimentale du *M. rhesus* au *Py. knowlesi* (Histopathological Lesions in Experimental *P. knowlesi* Infection in *M. rhesus*). Arch. Roumains Path. Expér. et Microbiol. Paris 1938. Mar. Vol. II. No. 1. PP. 33-84. With 33 figs. (17 coloured) on 17 plates. [107 refs.]

During the past three years in Rumania amongst other malarial studies the authors have investigated *Plasmodium knowlesi* infections in monkeys. The organs of a number of these animals which died of acute malaria or were killed at the height of their infection were utilized for histological studies. The results are carefully described in this paper which is illustrated by a series of 17 excellent plates 9 of which are in colour. The general conclusion reached is that the malarial infection in the monkeys is associated with an hypertrophy of the reticulo-endothelial system in those organs where the infected red blood corpuscles come into close contact with the histiocytes. This occurs chiefly in the spleen and liver and to a much less extent in the bone marrow. Even in the spleen it is chiefly in the cords of the spleen that the reaction occurs. It is much less marked in the venous Bulbroth where the hyperplasia occurs the histiocytes detach themselves and become free in the blood stream where they are carried to other organs and to the lungs. It is remarkable that the blood of the right heart contains a much larger number of these cells carrying the products of their phagocytosis than the blood of the left heart.

A point which is specially emphasized is the behaviour of the lymphoid follicles of the spleen. It is maintained that the lymphocytes do not become transformed into macrophages and that in those cases in which evidence of phagocytosis in the follicles is obtained it is carried out by certain histiocytes which are there and not by modified lymphocytes. The general tendency is for the lymphoid follicles to degenerate the surviving lymphocytes taking up a peripheral position. The lymphatic glands themselves behave in a similar manner and do not contribute to the defensive process. Similarly in the endocrine glands the histiocytes which do not come into intimate contact with the blood fail to respond. Haemoglobinuria being a feature of monkey malaria, the opportunity was taken of making a special study of the kidneys. The damage caused to the renal tubules and glomeruli are carefully described and illustrated. In general this is comparable to what occurs in human blackwater fever.

The investigation has been very carefully carried out and the paper should be studied by all those who are interested in the cellular reactions of malarial infections.

AFRIDI (M K) Observations on Extra-Abdominal Spleen in Monkeys Infected with *P cynomolgi* and *P knowlesi*—*Jl Malaria Inst of India* 1938 Dec Vol 1 No 4 pp 355-389. With 7 charts [21 refs]

By a surgical procedure the spleen of a number of rhesus monkeys was moved through an abdominal opening to a position on the pectoralis abdominalis muscle where it was allowed to remain in a subcutaneous situation. When the monkeys had recovered they were inoculated with either *Plasmodium knowlesi* or *P cynomolgi*. Observations were made on the increase in size of the spleen and the development of the parasites both in the peripheral blood and in blood taken from the spleen by puncture. In the case of *P cynomolgi* infections the chief enlargement of the spleen occurred one to four days after the parasites had reached their peak and had commenced to decline. Similarly when a relapse took place though parasites were few in number a considerable degree of splenomegaly occurred. In the case of *P knowlesi* infections the maximum enlargement of the spleen occurs before the height of the infection at which time a decrease in size may occur. In the case of *P cynomolgi* at the time of the crisis there is a marked irregularity in the cycle of development. The rate of increase in the number of parasites during the early stages of a *P knowlesi* infection in some cases appears to be greater than can be accounted for by the number of merozoites produced. This phenomenon is discussed without any explanation being offered. In the case of both parasites at the time of the crisis, abnormally small schizonts are liable to appear. Peripheral blood and spleen puncture blood were examined every two hours, and it was found in the case of *P knowlesi* infection that the peripheral blood was two hours behind that of the spleen as regards the number and stages of development of the parasites. There was thus a lag of two to four hours between the splenic and the peripheral blood.

CIUCA (M.) BADENSKI (G.) IONESCU (P.) & TERITEANU (E.) Contribution à l'étude du mécanisme de l'immunité acquise dans l'infection intentionnellement provoquée par le *Plasmodium knowlesi* chez l'homme. [Mechanism of the Immunity acquired in the Intentional Infection of Man with *P knowlesi*].—*C R Soc Biol* 1938. Vol. 129 No 34 pp 1234-1236

For the treatment of general paralytics the authors have employed the monkey malarial parasite *Plasmodium knowlesi*. It was observed that the majority of the patients after recovery from the malarial infection resisted entirely a second inoculation. In order to determine whether this was due to premunition or not two of these immune subjects were inoculated with a large dose of heavily infected blood. At intervals of 6 12 34 48 hours and 7 days 10 cc. of blood was taken and inoculated into susceptible monkeys. Only those receiving the blood taken after 6 hours became infected a result which proved that the inoculated parasites disappeared from the blood in between 6 and 12

hours. It would seem that after recovery from a *P. knowlesi* infection there is a definite immunity independent of a preinfection.

COGGESHALL (L. T.) The Cure of *Plasmodium knowlesi* Malaria in Rhesus Monkeys with Sulphanilamide and their Susceptibility to Re-infection.—*Amer J Trop Med* 1939. Nov Vol. 18. No. 6 pp 715-721

The author who has already published an account of experiments on the therapeutic effect of sulphanilamide on *Plasmodium knowlesi* infections in rhesus monkeys [this *Bulletin* 1938 Vol. 35 p. 897] in this paper describes further tests with this drug. In this case nine monkeys were used and treatment was commenced on the 4th to the 168th day of infection, parasites being demonstrable in the blood in all cases. In all cases the minimum dose being a single one of 1.0 gram given to one monkey parasites disappeared from the blood and daily examinations over a long period failed to indicate any relapse such as is frequent after quinine or atabrin treatment. As a further confirmation of cure blood was taken from the apparently cured animals and inoculated into clean monkeys. This again failed to reveal any latent infection though it is known that a single infected red cell is capable of giving rise to an infection. Furthermore, some of the treated animals were splenectomized without any infection being aroused. It is concluded that sulphanilamide in the cases treated completely eradicated the infection. All nine monkeys were subsequently re-inoculated. All became infected, but six recovered spontaneously an unusual result which indicated the existence of a residual immunity which was present as long as three months after the sulphanilamide treatment. The marked effect of the drug on *P. knowlesi* is contrasted with its failure in 30 cases of human *P. vivax* infections and in avian infections due to *P. lophurae* and *P. cathemerium*.

HELMINTHIASIS.

Précis of Abstracts in this Section

LEATHERS KELLER & MCPHAIL (p. 828) examined by the Stoll-Hau-beer technique nearly 30 000 residents in 543 rural communities in Florida and found a percentage infected with hookworms varying between 23 and 80 and in some districts observed a heavy infection to as many as 5 000 ova per cubic centimetre of faeces. SEHELT (p. 828) has reviewed the subject of hookworm infestation in Trinidad, dealing largely with its historical aspect. FERNANDEZ (p. 828) has done the same for Ceylon, but follows the historical introduction by recording the prevalence and importance of this infestation. In 1936 there were 1,839 deaths attributed to this cause and 258,720 cases were treated in the dispensaries. PEARSON & YANG (p. 829) from smear examination of a limited number of persons admitted to hospital found about 1 in 5 to be infested with hookworms in Shaoyang, Hunan. Some

provinces in Somaliland have been thought to be free from ankylostomiasis but MOISE (p 829) in the course of examining by the Willis technique 423 persons who had been negative to another found 45 per cent. positive and the relative proportions of *Necator* to *Ancylostoma* worms recovered about three to two. Infection by *Sch haematobium* was present in the same district.

D'ANTONI & ODOM (p. 829) describe a filtration (sieving) method of obtaining ova of helminths and cysts of protozoa from faeces and SAWITZ TOBIE & KATZ (p 830) have investigated the specific gravity of hookworm ova and find it to be for practical laboratory purposes approximately 1.055. DESCHIENS (p 830) describes a simple paper cone trap for obtaining larvae from a faecal culture.

PEERY (p. 831) gives an interesting account of the post mortem findings in three negroes dying after accidental poisoning by a mixture of carbon tetrachloride (1 part) and ethylene dichloride (3 parts) the one who lived longest had taken half a pint and died in 150 hours. FERNANDO and his colleagues (p 832) deduce after employing it in 41 adult persons with hookworm infestation that tetrachlorethylene had no toxic effect on liver kidneys heart or lungs but GUNewardene (p. 832) stresses the dangers of using this drug if it has undergone chemical changes, for phosgene is one of the products. Symptoms of intoxication by this were pallor shallow sighing respiration dim vision, impaired speech and drowsiness.

GARIN & ROMAN (p 833) rightly regard ankylostomiasis as an occupational disease among the miners in the Loire Valley and consider the question of prophylaxis on the usual lines of examination of workers (and prospective workers to prevent fresh introduction) and treatment by tetrachlorethylene of those found infested.

ROUBAUD & DESCHIENS (p. 833) record the interesting fact that certain fungi in their growth entangle and digest larvae of some species of nematodes among them those of *A duodenale*. This suggests the possibility of getting rid of infective larvae in the soil by seeding with these fungi e.g. *Dactyella ellipsospora*.

OTTO & KERR (p 833) record the results of their attempts at experimental immunization of dogs against *A caninum* by subcutaneous injection of living larvae.

Filariasis.—DASSANAYAKE (p 834) in a filariasis survey of Ceylon of which he is M.O. in charge found among 7,329 blood-smears taken between 9 p.m. and 1 a.m. a mean positive of 6.2 per cent. The proportions of *malays* to *bancrofti* were four to one. Galle leg is the common name in Ceylon for elephantiasis there but, although *bancrofti* is more common in Galle town this condition is due to *malays*. MITRA (p 834) found a case of *W bancrofti* infection in the Mikir Hills whereas in the North Cachar Hills about 100 miles further south, the prevalent *Filaria* is *malays*. VAN BEUKERING (p 834) makes an interesting observation. Examination of Mentawai Islanders in Sumatra did not discover any infected with filaria nevertheless he did find an *A. indones* in the convict barracks infected. He, therefore, examined the blood of the convicts (88 in number) and found three positive. He infers that the mosquito acquired it from one of the convicts who had come from Bandjermasin district. OLIVER A.G. & J. (p 835) note that filariasis is decreasing among the military but not among the civilians in Porto Rico. Twelve per cent of the soldiers were positive when their bloods were examined in 1903 only 3.7 in 1932 and 2.5 in 1937. It might be present without any clinical

[In the *précis* of the paper on filariasis by O'CONNOR and KNOTT in this *Bulletin* 1939 Vol. 36 p 143 it is stated that "These did not support their former conclusions that parturition in the adults is simultaneous and occurs about noon." This is incorrect. The *précis* should read as follows—"O'CONNOR and KNOTT (p 151) describe the pathological appearances in an excised varicose groin gland. Though supporting the view that parturition in the adults is simultaneous these appearances did not suggest that it always occurs about noon." C W.]

LEATHERS (W. S.) KELLER (A. E.) & McPHEAL (W. A.) An Investigation concerning the Status of Hookworm in Florida.—*Amer. J. Hyg.* 1939 Jan. Vol. 29 No. 1 Sect. D pp. 1-16. With 2 maps & 1 graph. [10 refs]

During 1937 and 1938 faeces were collected from 29,064 white residents of 543 rural communities in 56 counties of Florida. The faeces were then "stored at 40°C. until ready to be examined [an unusual step] the examination being by egg counts of 0.005 cc. of faeces suspended in 1 cc. of decinormal caustic soda solution the Stoll Hausbeer technique

The percentage found infected was 34.8 varying between 49.2 in the west 38 in the north-east 25.2 in the centre and 23.3 in the south though, throughout, the soil is favourable for development of hookworm larvae the more extensive agriculture and fruit growing in the south has improved the economic state and sanitary cleanness of those living there. Among 27,043 examinations analysed for sex and age the total, the male and the female percentages of infection were 34.4 38.4 and 30.8 the peak of infection by age lay between 15 and 19 years being 44.7 in total 51.5 in males and 37.7 in females though in these last it was 37.8 from 5 to 9 and again from 10 to 14 years. In the 10,126 faeces found positive the average number of eggs counted was 5,100 per cc. of faeces in 36.6 per cent of the positives the egg count was 2,600 or more, the level at which it is believed symptoms are likely to be present. It is estimated on this basis that in Florida 142,253 white persons have hookworm infection and 51,000 have hookworm disease. It was once more the case that the more persons in a family there were with hookworm infection the higher was the egg count per person. Of 4,121 faecal specimens got from negroes 19.9 per cent. were found positive with an average weight of infection of 1,800 eggs per cc. the age distribution was much as that for whites but the percentage who showed that egg count which is deemed sufficient to cause symptoms was a third of that shown by whites.

SEWELL (R.) A Historical Review of Ankylostomiasis in Trinidad.—*Caribbean Med. J.* 1938. No 1 pp 46-54

FERNANDO (P. B.) Ankylostomiasis in Ceylon.—*Jl. Ceylon Branch Brit. Med. Assoc.* 1938. Sept. Vol. 35 No 5. pp 365-376. With 2 charts.

After a historical survey the local importance of hookworm infection in Ceylon is stressed by the Registrar General's figures for 1936 namely 1,839 deaths, 14,693 cases treated in public hospitals, and 258,720 in

dispensaries. There follows consideration of symptoms clinical pathology (though here eosinophilia seems to have dropped out of a table showing typical findings in this infection) diagnosis treatment (where tetrachlorethylene is favoured and the importance of iron in defeating the anaemia is stressed) and prognosis with emphasis on the reticulocyte response C L

PEARSON (G H) & YANG (C T) Hookworm in Shaoyang, Hunan.—*Chinese Med J* 1938 Dec Vol 54 No 6 pp 574-578. With 1 map

Of 556 persons admitted to the Methodist Hospital Shaoyang Hunan in the first five months of 1938 112 or 20.1 per cent showed hookworm infection to a single smear. The authors have also analysed cases of infection from hospital returns for three previous years.

It is noted that this figure would obviously have been higher had concentration methods been employed. Of 374 cases of infection analysed for occupation nearly half were coolies or land workers while 73.1 per cent of infected were intimately connected with land. Of 404 cases analysed for sex men represented 94.4 per cent. [Apparently most of those attending hospital were males.] It is urged that by Government order all faeces should be stored for two months before being used on the soil as fertilizer not an impossible ideal since some farmers do so for their own purposes already. An easy way of getting a laugh from the farmer with his straitened means is to suggest that all working on the land should wear rubber boots.

C L

MOISE (Regolo) Osservazioni sulle elmintiasi d'interesse epidemiologico in Somalia (1932-1937) [Helminthiasis of Epidemiological Interest in Somaliland].—*Ann di Med Nav e Colon* 1938 Sept.-Oct. Vol 44 No 9/10 pp 444-451 With 2 plates

In 1933 there were examined 568 faeces in Provinces apparently free from hookworm infection. Of these 423 were examined by Willis's technique after having proved negative to ordinary examination presumably by smear and in 45 per cent of them eggs were found. Of 75 infected to whom carbon tetrachloride was given in unstated dose 12 passed no worms 46 passed fewer than 25 12 passed 25 to 50 4 passed 50 to 100 and 1 passed more than 100. Of 936 worms recovered 38 per cent. were ancylostomes and 62 per cent. necators. The word *anchilostoma* is used indifferently for hookworms in general or ancylostomes in particular. There are photographs showing familiar appearances of worms and sick.

Schistosomiasis was by *S. haematobium* but in addition to vesical infection its typical eggs were found twice in the faeces. C L

D'ANTONI (Joseph S) & ODOM (Vada) A Supplementary Basic Technique for the Recovery of Protozoan Cysts and Helminth Eggs in Feces. (Preliminary Communication).—*Public Health Rep* 1938 Dec 18. Vol 53 No 50 pp 2202-2204

A modification of the technique described in this *Bulletin* 1939 Vol 36 p 144

It having been discovered that hookworm eggs were held back when a faecal suspension was strained through a metal sieve with

60 meshes to the linear inch the original technique was modified so that the moist washed, faecal residue on the sieve was used instead of the original faeces. It was found that the sieve itself has little or no effect on retarding hookworm eggs since by putting a patient on a low residue diet only 0.2 per cent. of eggs are held back, while by adding gelatinous (i.e. adhesive) substances to the diet the percentage of eggs may be greatly increased by adding bran to the diet the percentage of eggs retained by the sieve reaches 4 per cent. In a normal diet the percentage of eggs remaining in the sieve is about 2.5 per cent.

[That hookworm eggs in watery suspension are themselves sticky was reported in 1908 by William Pepper, *Jl Med Res* Boston. This stickiness was the basis of the reviewer's diagnostic method, levitation [this *Bulletin* 1918 Vol 12, p 183 1919 Vol 13 p 208]. The great loss of eggs on straining through a wire sieve with 100 meshes to the linear inch was pointed out by the reviewer in comparing the results got from the same evened faecal suspension without and after such sieving [this *Bulletin* 1924 Vol 21 p 574 and *Trans Roy Soc Trop Med & Hyg* 1924 Vol 17 p 417 (Table X) this *Bulletin* 1929 Vol 26 p 605 and *Amer Jl Hyg* 1928 May Supp. p 33 (Table III)]. As compared with unstrained suspensions the strained ones showed respective losses in the three faecal specimens tested of 35, 54 and 60 per cent. of the eggs disclosed by the former but the former failed often greatly to show the real egg content of the suspensions for the numbers collected from them were respectively only 91, 31 and 48 per cent. of those disclosed by D.C.F.F.] C.L.

SAWITZ (Willi) TOBIE (John E.) & KATZ (Gertrud) The Specific Gravity of Hookworm Eggs.—*Amer Jl Trop Med* 1939 Mar Vol 19 No 2 pp 171-179 With 2 figs

1 By the use of the zinc sulphate buoyancy method the specific gravity of living eggs of *Necator americanus* has been determined to be approximately 1.055.

2 Dead hookworm eggs show a variation in their specific gravity probably due to the change in the permeability of the egg membrane.

3 Since the buoyancy method for the determination of the specific gravity of biological objects cannot avoid the possible interfering action of the chemical solution with the true density the specific gravity of 1.055 for eggs of *Necator americanus* is considered valid only for practical laboratory purposes and is not necessarily an intrinsic property of hookworm eggs.

[It is sixteen years since the reviewer found that for the practical laboratory purpose of diagnosis by D.C.F. (*Trans Roy Soc Trop Med & Hyg* 1923 Vol 16 p 274 Table V and this *Bulletin* 1923 Vol 20 p 847) a specific gravity of 1.150 was dependable for the floating of hookworm eggs while one of 1.100 was not.] C.L.

DESCHAMPS (R.) Procédé simple de récolte des larves strongyloïdes de nématodes dans les coprocultures. [Simple Method of collecting Strongyloid Larvae of Nematodes in Faecal Cultures.]—*Bull Soc Path Exot* 1939 Feb 8 Vol 32 No 2 pp 165-169 With 4 figs

The culture consists of faeces with an equal quantity of vegetable charcoal, animal charcoal, or wood ash incubated at 25°C. to 30°C. set

in a Petri dish. In its centre in a conical hollow is a cone of filter paper with 2 or 3 cc of water in it and this is the trap which the larvae reach. Evidently no attempt was made to discover its efficiency by comparing the number of larvae found in it with the number of eggs which had been present in the faeces. *A. duodenalis* and *S. fülleborni* were the nematodes concerned. C. L.

PEERY (Thomas M.) Carbon Tetrachloride Poisoning. A Study of Stages of Hepatic Damage and Repair in Man.—*Arch Pathology* 1938 Nov Vol. 26 No 5 pp 923-941 With 3 figs [49 refs.]

Three negroes found in 1935 a discarded tin of roach poison a mixture of carbon tetrachloride and ethylene dichloride in proportion of 1 to 3 and drank largely of it thinking it was alcohol the quantity taken by two was unknown that by the third who lived long enough in consciousness to be questioned was about half a pint they died respectively 6 to 11 63 to 68 and 150 hours after taking it

There is first considered the literature dealing with poisoning in man and of experimental studies in animals and then the symptoms and the lesions at autopsy. Case 1 was a negress of 65 who died in coma with blood urea nitrogen 44 mgm creatinine 2.6 mgm. and sugar 237 mgm. to the 100 cc and she had no lesions 2 days after death except scattered haemorrhages. Case 2 was a negro of 54 stuporous with blood-stained vomit blood urea nitrogen 63 mgm. creatinine 8.4 sugar 40 mgm. to the 100 cc and muscular twitchings autopsy immediately after death showed small haemorrhages particularly about the abdominal organs the microscope showed in the liver necrosis mostly in the central lobular zone where liver cells were replaced by red blood cells and where the reticulum fibres were disorganized there was no evidence of regeneration such as mitosis or the formation of young bile ducts. In the kidneys the greatest damage was in the cells of the convoluted tubes which were greatly swollen with granular cytoplasm and cell membrane indefinite. The capsular space was lined with swollen cells and itself contained fat droplets and eosinophil granular material which latter as well as red cells was present also in the lumen of the tubules. There was no tendency to form eosinophilic fibrils in the glomerulus as there is in glomerulonephritis. In the adrenals there was extreme vacuolation of some cells in the outer fascicular zone but no necrosis in the pancreas interlobular haemorrhage obstructed small ducts and small zones of necrosis were apparently related to these. There were haemorrhages too in heart lungs spleen small intestine and stomach the last having superficial cellular necrosis. The third patient aged 38 took as noted, about half a pint and vomited copiously and intermittently with blood in the vomit the liver's edge was 4 cm below the rib margin urea nitrogen of the blood 54 creatinine 8.2 sugar 82 serum calcium 8 mgm. in 100 cc of blood. At autopsy 12 hours after death there was jaundice numerous haemorrhages pneumonia in the lower lobes syphilitic aortitis the liver weighed 1 080 gm and on section was jaundiced soft and without normal structure the kidneys weighed 225 gm. each. Microscopically the central parts of the lobules of the liver had only collapsed stroma with some lymphocytes and red cells the peripheral parts had large cells with some mitosis and with bud like tubular projections pointing towards the centre of the lobule the

reticulum was condensed about the thickened central venule the kidneys showed rather more markedly the changes seen in case 2. It is pointed out that after poisoning by ethylene dichloride there has been moderate fatty degeneration of liver cells (but no necrosis), multiple haemorrhages and necrosis and calcification of epithelium of renal tubules.

FERNANDO (P B) D SILVA (Maurice) STORK (G K B) & SIVATAMBY (Grace R) Tetrachlorethylene in the Treatment of Hookworm Disease, with Special Reference to Toxicity.—*Indian J Med Res.* 1939 Jan. Vol 28 No 3 pp 759-783 [19 refs]

Tetrachlorethylene in view of its low toxicity and efficiency is a very valuable drug in the mass treatment of ancylostomiasis.

The determining of the presence of eggs, and the counting of their numbers before and ten days after treatment by undisclosed technique was the method used to test the efficacy of the drug. After being shaken up into a fine suspension in *Mistura alba* it was given to adults in doses of from 3 to 8 cc. In 41 cases, and the percentage of cures estimated in this way varied from 44-44 to 100 as the dose was increased. It is, however laid down as a prerequisite for assessing the value of an anthelmintic drug, that there must be known the numbers of worms originally harboured, those removed by treatment and those still present after it. [The first and third will be reliable only if there is a constant worm-egg ratio and the removal here reported by tetrachlorethylene of nearly 20 per cent. more ankylostomes from one patient than should have been there by the egg count is further evidence of the inconstancy of this ratio as to the second there was once more noted the complete disappearance of eggs from the faeces with no worms passed, the host having evidently at last fed on the worms that had for long fed on him.] After determining the icterus index, the van den Berg reaction and the presence of bile salts, bile pigment and urobilin in the urine, and using the bromsulphalein, and the laevulose tolerance tests it is concluded that the drug has no toxic effects on liver kidneys, heart or lungs. Yet a few of those who received doses of 8 cc. or more showed temporary untoward effects as of an overdose of a narcotic drug. Children may be given tetrachlorethylene in doses of 4 to 5 times the age in minima.

C L

GUNewardene (S R) Decomposition of Tetrachlorethylene.—*Jl Ceylon Branch Brit. Med Assoc.* 1939 Jan Vol 36 No 1 pp 22-24

Quart bottles of tetrachlorethylene were noticed to fume when opened on receipt from the makers, and to have a pungent smell. The Government analyst reported phosgene present and none of the drug was administered, but earlier serious symptoms had followed administration of this drug in an estate with 250 labourers fortunately none fatal. The symptoms were rapid small pulse with pallor shallow and sighing respiration indistinct speech dimness of vision and drowsiness.

GARIN (Ch) & ROMAN Prophylaxie de l'anquilostomose des mineurs dans le bassin de la Loire [Prophylaxis of Ankylostomiasis in Miners of the Loire Valley]—*Ann d Hyg Pub Indust et Sociale* 1939 Feb Vol 17 No 2 pp 56-66 [Refs in footnotes.]

Ankylostomiasis in French miners is an occupational disease. Some of its symptoms and its life cycle are sketched. Prophylaxis should be by discovery and treatment of the infected for the former reliance being placed on a modified Telemann technique for the latter on tetrachlorethylene C L

ROUBAUD (Emile) & DESCHIENS (Robert) Capture de larves infectieuses de nématodes pathogènes par des champignons prédateurs du sol [The Capture of Infective Larvae of Pathogenic Nematodes by Predatory Soil Fungi]—*C R Acad Sci* 1939 Jan 23 Vol 208 No 4 pp 245-247

Will it prove possible to destroy infective larvae of hookworms and strongyloides present in and on the soil by seeding this with certain microscopic fungi?

This paper deals specially with the free living larvae of *Strongyloides fulleborni* from the chimpanzee and of *Ancylostoma duodenale* from man while the fungi were of five species *Dactylaria brochopaga* *Dactylella benibicoides* *Dactylella ellipsospora* *Arthrobotrys oligospora* and *Stylopaga hadra*. Members of these genera produce in the presence of these among other nematodes structures of a strangling or glutinous nature which capture these nematodes by a sudden enlargement of the cells which come in contact with the worms and digest them in 36 to 48 hours. Although the diameter of these larvae is as much as eight times that of the mycelium and though the strands of the latter may rarely be broken the larvae do not escape digestion C L

ROUBAUD (E) & DESCHIENS (R.) Destruction de larves infectieuses d'anquilostomes et d'anguillules intestinales par *Dactylella ellipsospora* [Destruction of Infective Larvae of Ankylostomes and Strongyloides by *D. ellipsospora*]—*Bull Soc Path Exot* 1939 Feb 8 Vol 32 No 2 pp 160-165 With 5 figs. (4 on 2 plates)

OTTO (G F) & KEER (H B) The Immunization of Dogs against Hookworm, *Ancylostoma caninum* by Subcutaneous Injection of Graded Doses of Living Larvae.—*Amer J Hyg* 1939 Jan Vol 29 No 1 Sect. D pp 25-45 With 4 graphs [29 refs.]

Immunization was by bi weekly hypodermic injection of living infective larvae of *A. caninum* in numbers increasing from 15 to as much as 60 000 with an infective dose of 120 000 to 200 000 five to seven months later. Before and during the period of experiment the faeces were watched by DCF for the appearance of eggs and these were numbered by the Stoll Hausheer method. The immunized animals were killed on day 35 all but one of the non immunized animals died before day 14.

Three litters of dogs, a total of ten animals were used to demonstrate the sharp difference between the active immunity to hookworm resulting from serial light infections and the partial refractoriness of mature dogs to initial infections. From 52 to 203 worms were recovered at autopsy from

actively immunized dogs given test doses of 120 000 to 200 000 larvae whereas, the unprotected litter mates produced 1,283 to 31 200 worms. Furthermore, the unprotected animals, with one exception, succumbed to the test infections whereas, the immunized animals were scarcely disturbed. In the discussion of these results and the previous work on dog hookworm it was concluded that there is nothing distinctive about the so-called age resistance but rather that maturity and generally good health are essential for the host to respond fully and quickly to the stimulus of invading worms : i.e. actively to acquire immunity.

[The note that immunized animals were scarcely disturbed perhaps applies to clinical state for in two immunized dogs the lungs were found almost solid with grey hepatization. The conclusion that maturity and general good health are essential for the host's proper response to infection is unlikely to apply to man in face of the findings as between white persons and negroes by LEATHERS KELLER and McPHAIL, see above p. 824.] C. DASSANAYAKE (V. L. P.) A Note on Filariasis in the Southern Province, Ceylon, 1938.—*Jl. Trop. Med. & Hyg.* 1939 Feb 15 Vol 42 No 4 pp 61-63.

This report of the Medical Officer in charge of the Filariasis Survey Ceylon covers 7,329 blood smears made in three Districts between 9 p.m. and 1 a.m.

The percentage of positive examinations was between 0.6 and 14 mean 6.2. Of the infections, 80 per cent. were with *Mf. malayi* and 20 per cent. with *Mf. bancrofti*. The Pistia plant and *Mansonia uniformis* are abundant where the infection is by Malayan filariasis. *Culex fatigans* carries the Bancroftian form which is prevalent in Galle town. So well known locally is the association of filariasis with this town that Galle leg is the name in Ceylon for elephantiasis of that limb yet this is a lesion caused by the Malayan infection which does not cause genital infections. C. L.

MITRA (P. N.) Filariasis in the Mikir Hills.—*Indian Med. Gaz.* 1938 Dec Vol 73 No. 12 p 740 With 1 fig.

In the Mikir Hills, lying in the Districts of Silbagar and Nowgong south of the Brahmaputra, the blood from one filarial patient was reported on in the School of Tropical Medicine Calcutta as containing embryos which appear to be *Mf. bancrofti* whereas in the North Cachar Hills *Mf. malayi* prevails. C. L.

VAN BEUCKERING (J. A.) Filarialarve in een *Anopheles ludlowi* [Filarial Larvae in *Anopheles ludlowi*].—*Geneesk. Tijdschr. v. Nederl.-Indië* 1939 May 2 Vol 79 No 18 p. 1114.

Experimentally IYENGAR and RAO in 1932 were able to infect a high proportion of *A. ludlowi* var. *truxalis* with filarial embryos mature

larvae being found in 10 days in 28 out of 41 specimens [see this *Bulletin* 1933 Vol. 30 p 227] Examination of 150 inhabitants of the Mentawai Islands Sumatra by BOERS KLYN and BOON VAN OSTADE revealed none infected and the author himself examined 41 with the same result He did however find an infected specimen of *A. ludlowi* in the convict barracks and consequently examined the blood of the convicts 86 in number and found three infected all of whom had come from Banjermasin district The mosquito must he states have infected itself from one of the convicts H H S

OLIVER (Andrés G.) & OLIVER (José) Filariasis In Puerto Rican Soldiers. A Survey.—*Puerto Rico Jl Public Health & Trop Med* 1938 Sept Vol. 14 No 1 pp 18-20 [Spanish version pp 21-23]

Comparison of the results of three surveys made on Porto Rican soldiers in 1903 1932 and 1937 leads to the conclusion that filariasis is disappearing rapidly from the soldiers

In 1903 ASHFORD found microfilariae in the blood of 12 per cent of 250 soldiers stationed at Cayley a hill station who before enlistment had lived in crowded towns and a large proportion had presumptive evidence of infection before entering the service In 1932 ASHFORD and SVYDER examined 480 native soldiers stationed at San Juan and found microfilariae in the blood of 3.7 per cent In 1937 the authors surveyed 794 men 544 stationed at San Juan with 2.5 per cent positive for microfilariae and 250 at Cayley with 0.4 per cent (1 man) positive moreover 11 of the 18 men positive in 1932 were still in the service and 10 of them had no symptoms and no microfilariae in the blood It is pointed out that there is no such lessening of infection in civil life ASHFORD in 1902 estimated 10 per cent of the population of Ponce as infected O CONNOR and HULSE found infection in 28.3 per cent. of 2 098 persons in Porto Rico in 1929-31 and TAMPE 7.7 per cent. of 518 persons in Santurce in 1931 C L

HU (Stephen M. K.) Preliminary Observations on the Effects of Filarial Infection on *Culex pipiens* var *pallens* Coq.—*Chinese Med Jl* 1939 Feb Vol. 55 No. 2 pp 154-161

A report on 200 infected *C. pipiens pallens*

The data so far obtained appear to indicate that the mosquitoes which were able to survive longest in the infected lots were generally either those that were negative to infection or those that were harbouring few larvae. However those that succumbed soon after the completion of the incubation period consisted of many lightly infected as well as the heavily infected specimens.

HU (S. M. K.) Observations on the Development of Filarial Larvae during the Winter Season in Shanghai Region.—*Amer Jl Hyg* 1939 Mar Vol. 29 No 2, Sect. D pp 67-74 With 3 figs.

"1 It was experimentally found that, under winter conditions in Shanghai during 1935-36 few of the microfilariae ingested by *Culex pipiens* var *pallens* from a case of *Wuchereria bancrofti* infection were able to penetrate into the coelomic cavity of their mosquito host For example 57 living and 54 dead microfilariae were present in the stomach contents

of a mosquito dissected on the twelfth day after its only infective feed. [The latter sentence is taken from the text itself.] Those which succeeded were found unable to undergo development in the mosquitoes.

" 2 Some infective filarial larvae which developed from experimentally infected *Culex pipiens* var *pallens* during the latter part of November were found able to survive in their mosquito hosts until about the middle of the following March.

3 That the infective filarial larvae would be able to survive longer in the *Culex pipiens* var *pallens* if they were not exposed to the low temperature prevailing during the winter season was indicated by the results of an experiment whereby some of the infected mosquitoes were kept in a slightly heated room while others were kept in an unheated room.

HU (S. M. K.) Studies on the Susceptibility of the Shanghai Mosquitoes to Experimental Infection with *Wuchereria bancrofti* Cobbold. VI. *Culex rapax* Wiedemann.—*Peking Nat. Hist. Bull.* Peking 1938 Vol 13 Pt 2 pp 113-118. [Summarized in *Rev. Applied Entom.* Ser. B 1939 June Vol. 27 Pt 6, p 124.]

During 1934-35 experiments similar to those already noticed were undertaken in Shanghai to determine the susceptibility to infection with *Filaria* (*Wuchereria*) *bancrofti* of females of *Culex rapax* Wied. reared from larvae collected locally. Of the 206 mosquitoes dissected 13-21 days after the infecting feed 189 harboured infective larvae. The average number of larvae per infected mosquito was 10.2. Infestation was exceptionally heavy in a few of the mosquitoes, and one dissected 13 days after the infecting feed harboured 111 infective larvae. The normal completion of development of so many larvae is considered to indicate that this species is a very suitable intermediate host. When a series of *C. rapax* was fed at the same time as a series of *C. pipiens* var *pallens* Coq. on the same infected person 74 out of 78 of the former and 47 out of 49 of the latter were found to harbour infective larvae after 12-18 days, the average number of larvae per infected mosquito being 10.9 and 9.3 respectively.

YOKOGAWA (Sadamu) Studies on the Mode of Transmission of *Wuchereria bancrofti*.—*Trans. Roy. Soc. Trop. Med. & Hyg.* 1939 Feb 28 Vol 32 No 5 pp 653-668. With 4 figs. [13 refs.]

— Investigations on the Mode of Infection of *Wuchereria bancrofti*.—*Japanese J. Med. Sci.* Pathology 1939 Vol 3 No 3 pp 167-181. With 6 figs. on 1 plate. [14 refs.]

These two papers on the transmission of *W. bancrofti* cover the same ground and largely use the same words in doing so. They deal with the question whether besides the mosquito in which the larva develops there is a second host in which it lies in wait for a chance to infect man.

After a historical survey, the experiments done in Yokogawa's laboratory by ABE [this *Bulletin* 1938 Vol 35 p 399] are tabulated; they were made to determine the viability of infective larvae in various media. When these larvae were placed in water with *Cyclops leuckarti* and *C. fimbriatus* they were eagerly eaten and completely digested, and though rarely eaten by *Diaptomus* they were as fully digested when they were not were other forms of animal life which frequent domestic water cisterns implicated. It was observed that larvae live longer in water at room temperature than at body temperature—a phenomenon "unreported by a previous observer." [It

falls into line with the observation (BAHR *Filariasis and Elephantiasis in Fiji* Report to the London School of Tropical Medicine 1912 pp 182-183) that microfilariae live in citrated blood for 3 days at room temperature and for 12 hours at 37°C. In monkeys fed with infective larvae placed on a banana or having had these introduced into a loop of jejunum no trace of infection could be found in the body. In 569 persons examined in the village of Ohama on Ishigaki Island there were from 8 to 20 years of age quinquennial percentages of infection of 22.92, 21.14 and 26.69. It is evident that the rate per 5 year period increases extremely slightly so that it may be assumed that fresh infections rarely occur. Consequently even if we admit the mosquito to be the vector filariasis does not spread as rapidly as does malaria which is known to be transmitted by anopheles. Comment is not made in the script of the fact that the respective decennial infection rates between 21 and 50 were 44.64, 53.85 and 56.00. Of 221 female *Culicines* two were infected the low infection rate for a heavily infected region throwing doubt on the rôle of the mosquito as vector. Larvae of an unstated sort obtained from two mosquitoes (? by dissection) failed to enter the abdominal wall of a pup or the ear of a mouse when the skin was intact but when a mouse was treated by the depilatory *Eva* cream and the skin then needled one larva was found in the subcutaneous tissue. After mosquito bites larvae were found on and in the skin and in one case (illustrated) it is believed that the larva entered through the mosquito puncture. It is concluded that the spread of the disease is largely a matter of chance its transmission being limited by a number of adverse factors. C. L.

YOKOGAWA (Sadamu) & YOSHINO (Takayoshi) On the Spread of *Wuchereria bancrofti* and its Relationship to the Human Flea, *Pulex irritans*.—*Taiwan Igakkai Zasshi* (Jl Med Assoc Formosa) 1938. Oct. Vol. 37 No 10 (403) [In Japanese pp 1540-1543 English summary p 1544.]

Since the extensive distribution of Bancroftian filariasis is yet not as extensive as that of *Culex fatigans* these writers in the hope of finding another larval host experimented with *Pulex irritans* (363 male and 528 female fleas). All larvae found in the fleas were in clots in the midgut and apart from unsheathing were unchanged. It is concluded that the human flea has nothing to do with the spread of filariasis. C. L.

GALLIARD (H.) Sur la biologie des culicidés du genre *Mansonia* R. Blanchard en Indochine. [Biology of *Mansonia* Species in Indo-China.]—*Ann Parasit Humain et Comparé* 1939 May 1 Vol 17 No 3 pp 177-188 With 1 text fig & 6 figs. on 2 plates [14 refs.]

The three species of *Mansonioides* which occur in Indo-China *M. indianus*, *M. annulifera* and *M. uniformis* are probably concerned in the transmission of *Microfilaria malayi* and *Wuchereria bancrofti* though conclusive evidence is lacking. In Tonking the larvae of these mosquitoes are associated much more commonly with the water hyacinth *Eichhornia crassipes* and with the submerged leaves of *Salvinia natans* than with the water lettuce *Pistia stratiotes*. In the south on the other hand, in Cochinchina and Cambodia they are

associated chiefly with *Pistia*. The author has not confirmed the observation that decaying vegetation is necessary for the development of the larvae. He has also obtained transformation from fourth stage larvae to adults in distilled water without any plants. Apparently the larvae and pupae can on occasion obtain oxygen directly from the water surface like other genera of mosquitoes. *V B Wigglesworth*

MEYERS (F M) & KOUWENKAAR (W) Over hypercoenophilie en over een merkwaardigen vorm van filariasis. [Hypercoenophilia and an Unusual Form of Filariasis].—*Geneesk. Tijdschr. v. Nederl. Indië* 1939 Apr 4 Vol 79 No 14 pp 853-873 With 8 figs on 2 plates [22 refs.] English summary

In seven Javanese men the authors observed a general swelling of the superficial lymphatic glands with particularly severe tumefaction of the glands in and under the groin, associated with a severe coenophilia of the blood. In the excised glands from the groin eosinophilic abscesses were found, containing a small worm with all the characteristics of a microfilaria. In some cases at the periodical observations over a period of 3 years or more no filaria could be found in the blood and the coenophilia remained constantly on a high level. Some patients had an inflammation of the glands with purulent discharge. No symptoms of filariasis malaya or Bancrofti could be found. No adult filariae were seen in the excised glands. The clinical, anatomical and parasitological findings do not permit a definite diagnosis as to the species of filaria involved. Also the epidemiology gave no help in their determination, the cases all occurring in a non-endemic area.

Two patients suffered from asthma bronchiale and two from a haemorrhagic nephritis. It is suggested that these 2 symptoms together with the coenophilia may have a common allergic origin, brought about by the filarial infestation.

BOXER (C) Over hypercoenophilie in de milt gecombineerd met een filaria infectie. [Hypercoenophilia and Filaria Infection of the Spleen].—*Geneesk. Tijdschr. v. Nederl. Indië* 1939 Apr 4 Vol 79 No 14 pp 874-876 With 2 figs. on 1 plate English summary

Description of an infestation of the spleen-tissue with microfilariae in a Javanese man, who was killed in a motor-car accident. The presence of the microfilariae was discovered during the routine histological examination of the internal organs. Nothing is known about the presence of microfilariae in the patient's blood. The other internal organs were negative however. The spleen had reacted with an extraordinary degree of coenophilia and some peculiar giant cells were noted, surrounding the terminal ends of the larvae. The extreme degree of coenophilia, for which no other explanation is available must have some connection with the presence of the microfilariae. It represents either an undescribed phase in the life of one of the common filarial species or a manifestation of an unusual filarial parasite and altogether this condition is in many ways comparable to the coenophilic microfilarial manifestations in lymph glands described by MEYERS and KOUWENKAAR in this same number.

MAKAR (Neguib) On Filariasis of the Intrascrotal Structures.—*Jl Egyptian Med Assoc* 1938, Nov Vol 21 No 11 pp 682-715 With 17 figs (15 coloured on plates) & 11 microphotographs. [37 refs.]

A report on 10 cases of endemic funiculitis, and on 38 out of 100 cases of chronic intrascrotal swellings not gonorrhoeal in origin and

operated on during the last four years and which were filarial in origin

Of the acute cases 1 was gangrenous 1 was non-suppurative and 8 were suppurative. The microscopic appearances were those of sepsis intratesticular haemorrhage and lymphocytic infiltration. In 3 gangrenous or acute suppurative conditions with orchidectomy no worms could be found. In a fourth orchidectomy the lesions were essentially those of chronic affection in a man with urinary bilharziasis subsequent examination showing many filarial worms in the cord lymphatics with in some parts histological findings peculiar to suppuration. In no other case were these worms found in the spermatic cord. In comment Makar concludes that worms in the cord lymphatics may die and be absorbed without trace if they remain sterile bacterial infection of different grades of virulence may be superadded, and equally here worms may die and be absorbed the effects on the various intrascrotal structure are considered.

Of the 38 chronic filarial lesions 19 affected the cord alone 6 cord and epididymis 3 cord, epididymis and tunica 4 the epididymis alone and 6 the tunica alone. They are considered under the anatomical headings concerned symptomatology diagnosis and treatment. As to the last the value of the sulphonamide group in bacterial infections is noted as is the risk that X rays may damage the testis. In surgical treatment it is urged that the surgeon should not forget that he is dissecting lymphatics the collateral circulation of which might already have been overtaxed by previous inflammations. Excision should therefore, as much as possible be restricted to the diseased tissues.

The reproductions of the microphotographs are not clear those of the paintings are vivid.

POYNTON (J. Orde) & HODGKIN (E. P.) Two Microfilariae of the Kra Monkey (*Macaca irus*)—*Trans. Roy. Soc. Trop. Med. & Hyg.* 1939. Jan. 28 Vol. 32. No. 4. pp. 555-556.

Of these two microfilariae from *Macaca irus* one is indistinguishable from *Mf. malaya* and was found in one of eleven monkeys examined. Of species of *Mansonia* fed on this monkey infection took place in four of six *M. annulifera* in 18 of 21 *M. longipalpis* and in 34 of 36 *M. uniformis*. In all but one mosquito mature larvae were found on the tenth day. Attempts are being made to infect monkeys of this species with this infection derived from man and to trap others for dissection in order to recover the adult worms.

The second microfilaria is about 600 μ long and 5 μ wide, and probably the adult is not a parasite of man. C L.

UNDERWOOD (Paul G.) & HARWOOD (Paul D.) Survival and Location of the Microfilariae of *Dirofilaria immitis* in the Dog.—*Jl Parasitology* 1939 Feb Vol. 25 No 1 pp. 23-33 [19 refs]

1 An uninfected dog was transfused intravenously with blood containing approximately 233 000 microfilariae of *Dirofilaria immitis*.

2 The microfilariae survived in the blood stream of this dog for more than two years.

3 At autopsy about 2½ years after the injection of the microfilariae, no embryos could be found in the blood.

4 No increase in size of the embryos was noted at any time.

5 As other authors have noted, comparatively few of the introduced microfilariae appeared in the peripheral circulation following injection.

6 Lane's hypothesis that most of the artificially introduced microfilariae are removed by the cells of the reticulo-endothelial system and subsequently destroyed, is not substantiated.

7 Available evidence indicates that a part of the microfilariae are concentrated in the capillary networks throughout the body and a part leave the blood stream altogether this is possibly true for all microfilariae in the blood stream, whether sheathed or unsheathed.

8 Whether or not the microfilariae live for long periods under natural conditions in the presence of adult worms cannot be ascertained on the basis of a reliable data. There is evidence that the macrophage system, acted by some type of immunological reaction, may destroy large numbers of microfilariae in a short time, but there is also evidence which suggests that such reactions are of irregular occurrence and that they do not regularly affect microfilarial longevity or periodicity.

[The conclusions in paras 5 and 6 seem contradictory. In the experiment cited in the paper microfilariae were injected into the dog's blood in numbers corresponding to 100 per cc. of its total estimated volume. By next day the numbers were reduced to 4 per cc. most microfilariae had certainly been removed from the circulating blood. That the young of *M. bancrofti* are destroyed in numbers by the reticulo-endothelial cells is something more than hypothesis. There are the visual observations first that these cells are greatly increased in numbers in those parts of that system where microfilariae and other young filarial forms are especially collected, and second that many of these parasitic forms are markedly degenerate there. It is a conclusion which I think will be generally drawn. No visual evidence for para 7 is offered, the statement is inference. To suggest that there must be a hiding place used by *M. bancrofti* by day which yet has escaped detection by workers in tropical medicine for 50 years seems to reflect little credit on a band of able men.] C L.

AUGUSTINE (Donald L.) Observations on the Occurrence of Heartworms, *Dirofilaria immitis* (Ledy 1856) in New England Dogs.—*Amer Jl Hyg* 1938 Nov Vol. 28. No. 3 pp. 390-395 [10 refs]

One of the observations on this dog filariasis merits remembrance for human infections. Microfilariae were found in the blood of two cocker spaniel pups five months old. According to HALL, PRICE and WRIGHT (1934) maturity is not reached till this parasite is eight months old. Either this interval is at least not invariable or prenatal infection occurs. C L.

MOLSER (H) *Filaria perstans*—Arch f Schiffs u Trop Hyg
1939 Mar Vol. 43 No 3 p 130

Acanthocheilonema perstans is not a harmless parasite. It causes fever as high as 38° to 39°C (since this is attributable to no other cause) and the microfilariae disappear from the blood under intra-venous injections of 1 per cent. methylene blue beginning with doses of 2 cc. and rising to 10 cc. It at least merits investigation as to whether this parasite can cause illness. C L

EAST AFRICAN MEDICAL JOURNAL. 1939 Feb Vol 15 No 11
pp 369-377 Onchocerciasis [In East Africa]

A symposium of onchocerciasis in Equatorial Africa largely historical and already dealt with in this *Bulletin*. A letter from HAWKING reports that at Kakamega, Kenya he examined two groups of persons. The one consisted of 52 prisoners and mine labourers selected on account of possible eye trouble in them *Onchocerca* microfilariae were found evidently in the skin and nodules in the upper part of the body in 7. The other group was of 53 patients taken at random in a native hospital and in them these microfilariae were found in 20 and nodules in 1. C L

HARLEY MASON (R. J.) Filarial Blindness in Kenya—*East African Med J* 1939 Feb Vol 15 No. 11 pp 363-368.

Three cases are reported all coming from the Kakamega district of Kenya, in all of whom there were the ocular symptoms and ocular lesions associated with *Onchocerca* infection and a heavy eosinophilia, while in two of them *Onchocerca* larvae were recovered from the skin. Reference is made to HAWKING's findings in this district [see above]. C L

GOPSILL (W. L.) Onchocerciasis in Nyasaland.—*Trans Roy Soc Trop Med & Hyg* 1939 Jan 28 Vol. 32. No. 4 pp 551-552.

A report on 20 cases of onchocerciasis in the district of Cholo in the Shire Highlands.

No patients have been seen from Lower Shire or North Nyasa in the lowlands. In the fast flowing highland streams *Simulium damnosum* is found. In seven of the patients with nodules frequent and extensive blood examinations failed to disclose embryos and the same result followed examinations of 850 persons (even to the extent of five films every other day for 10 days) living in infected parts. In the same way 100 lymph smears from the 20 patients and from 80 others failed to show any microfilariae but these were once found in the blood during the actual removal of a cyst and again four hours later in a node puncture done in this person. No nodules in this geographical area were found in the scalp neck and upper limbs nor were there disturbances of vision or symptoms attributable to infection in the central nervous system although in one with a family history of epilepsy the attacks began when nodules appeared near the ninth rib mid axillary line and near the coccyx and disappeared when these tumours

were removed. In the same way where there has been referred pain it has disappeared with removal of the nodule concerned. Excised nodules have commonly contained four male and eight female worms.

DUBOIS (A.) VITALE (S.) & BIRGER (Ch.) Contribution à l'étiologie de l'éléphantiasis congolais. Région de Betongwe-Chefferie Medjeje [The Aetiology of Elephantiasis in the Congo]—*Ann Soc Belge de Méd Trop* 1939 Mar 31 Vol. 19 No 1 pp 27-31

Microfilariae in the skin are fairly frequent in cases of elephantiasis in the Medjeje chieftainship. *Mf rostratus* in genital elephantiasis and *Mf streptocerca* in that of the lower limbs, but the fact that the former has a low percentage among the sick and the latter is very abundant in the healthy does not allow of the conclusion that these filariae alone are the cause of the elephantiasis.

C. L.

DUBOIS (A.) & FORRO (M.) Contribution à l'étiologie de l'éléphantiasis congolais. Le rôle de *O rostratus* étudié au Nepoko [The Aetiology of Elephantiasis in the Congo. The Role of *O rostratus*.]—*Ann Soc Belge de Méd Trop* 1939 Mar 31 Vol. 19 No 1 pp 13-21

The investigations lead to the conclusion that *Onchocerca rostratus* favours the appearance of elephantiasis but is not its primary cause. In this region some 80 per cent of persons show *Onchocerca* nodules, in 73 inhabitants examined at night *Mf bancrofti* was absent and in 56 per cent. of persons with genital elephantiasis no *Onchocerca* nodules were found in spite of very close examination.

C. L.

DÉJOU (L.) Suppuration d'un kyste à onchocercques (*Onchocerca rostratus*) [Suppuration in an *Onchocerca* Cyst.]—*Bull Soc. Path Exot* 1938 Oct 12. Vol 31 No. 8 pp. 725-728

A swelling in the left buttock with fever and pain was incised and some cubic centimetres of turbid fluid escaped. Next day a bunch of worms lay on the dressing identified by ADVIER as *O rostratus* and one or two continued to be passed daily. The tumour was excised and proved to be an irregular fibrous mass "as large as a nut [volume global d'une noix] in the subcutaneous tissue adherent to the muscle loculated on section with *Onchocerca* worms in cavities.

C. L.

ADVIER & DÉJOU (L.) Arthrite aiguë du genou avec présence d'embryons d'*Onchocerca rostratus* dans le liquide articulaire [Acute Arthritis of the Knee. *Microfilaria rostratus* in the Articular Fluid.]—*Bull Soc Path Exot* 1938 Oct. 12. Vol. 31 No 8. pp 727-730

There was in fact a double parasitism with *Onchocerca* and *Dracunculus*.

The *Onchocerca* showed itself by acute arthritis of the left knee with many *Mf rostratus* in the synovial fluid, which contained many polymorphs but no bacteria on culture and behind the knee in the

popliteal space by a tumour which excision showed to be a subfascial cyst containing adult *O. volvulus*. The Dracunculus infection showed itself later under the left ligamentum patellae above the right internal malleolus another worm a little higher up a fourth on the right thigh and a fifth on the right heel. In the sinus where the third worm pointed there were embryos of *O. volvulus* as well as of *D. medinensis*. It is stressed that two examinations made at an interval of two days have shown one many microfilariae the other none. C L

Two cases of streptococcal inflammation in the knee joint were certainly and a third was probably associated with an adjacent guinea-worm. In two the joint was afterwards left rigid in the third it could be bent to a right angle. C L

GALLIARD (Henri) Unité ou pluralité des *Strongyloides*. [Are there One or Many *Strongyloides* Species?].—*C. R. Soc Biol* 1939 Vol 130 No. 5 pp 413-416

This discussion of the writings of various workers points out the structural similarity of *Strongyloides* species from different animals and in considering the question of acquisition of infection by man from the dog points out the complexity of the epidemiology—the result of the great instability of types which come from different sources. C L

DE PAULA E SILVA (Geraldo Siffert) *Estrongyloidiasse* duodenal. [*Strongyloides stercoralis* in the Duodenum.].—*Brasil-Médico* 1938, Sept 10 Vol 52 No. 37 pp 835-839 English summary

Examination of material aspirated from the duodenum proved a far more certain means of diagnosis of strongyloides infection than did faecal examination.

Of 1942 persons examined all in good circumstances 17 were found infected with strongyloides. 13 of these showed larvae in the duodenal contents only 2 in the faeces only and 2 in both. In 11 there was complaint of pain in the upper abdomen fullness or weight after food salivation or diarrhoea. All were nervous local epigastric tenderness was present in 6. X rays showed evidence of duodenitis in 2 while the microscope gave evidence of irritation or inflammation in 9. There was hyperchlorhydria in 2 achlorhydria in 4 and normal values in the rest. C L

SIMPSON (Virgil E.) *Strongyloidiasis*.—*Jl Amer Med Assoc* 1939
Mar 4 Vol. 112 No. 9 pp. 828-832. [34 refs.]

The treatment by compound solution of iodine was carried out successfully in 9 cases as follows —

"A saline purgative was administered one hour before supper. This was expected to act before the patient a bedtime. Breakfast was withheld the following morning. A transduodenal tube equipped with a Lyon metal bulb was introduced, the stomach irrigated and the tube allowed to pass into the duodenum. The duodenal contents were aspirated for the twofold purpose of securing a specimen for laboratory examination for parasites and to remove contents, thus lessening the dilution of the drug to be introduced into the bowel.

Compound solution of iodine was then introduced into the duodenum and the tube withdrawn. The dose finally fixed was 60 minims (4 cc.) and was given on alternate days until neither the duodenal contents nor the feces showed ova, parasites or larvae. After two weeks the duodenal contents and feces were examined. If the results were negative the patient was instructed to return in one month for another laboratory study.

An energetic mop-up campaign of washing scrubbing, sunning, painting, and liming the treating or killing of all household pets and the examination and treatment if necessary of all members of the family are held to be essential measures.

Examination of the water supply has shown no ova in my experience."

[Liq Iodi. Co. U S has the composition Iodine 5 potassium iodide 10 water to 100 and is approximately the same as Lugol's solution, the dose of which is minims 5 to 10] C L.

TORRES (C Magarinos) & DE AZEVEDO (A Penna) *Lesões produzidas no homem por Strongyloides Sobre a hyperinfection* [Lesions produced in Man by Strongyloides. On Hyperinfection].—*Livro Jubilar do Prof L. Travassos* Rio de Janeiro. 1938. pp. 475-483. With 9 plates [24 refs.]

There are described the findings at autopsy in two persons with strongyloides infection and in whom the larvae (born presumably in the intestinal canal) had penetrated into the wall of the colon in great numbers and had been carried thence to lymph nodes, liver and lungs.

It is believed that all the larvae were in the rhabditiform stage. They entered the wall of the colon through ulcers of which there were a number (that is to say many larvae were found at their bases) but they were found also where there were no ulcers and they crept down Lieberkühn's glands and seemingly entered the connective tissue at the ends of these. In this tissue they caused diffuse haemorrhage and infiltration with polymuclear eosinophil, macrophage and giant cells. This region they left by lymph or blood escalator. Those travelling by lymph were apt to penetrate into the walls of the lymph vessels and cause subendothelial nodules while in a lymph node there was giant cell formation. Those which entered the blood stream might produce thrombosis in the coeliac veins, the clot being invaded by lymphocytes and macrophages. Larvae which had reached the liver might be found within the walls of the portal veins or in the portal spaces, surrounded by a cellular exudation. In the lungs [which they may clearly have reached by either blood or lymph escalator] they broke through into the alveoli and blood escaped with them. The illustrations are convincing C L.

SCHENKEN (John R.) & MOSS (E. S.) *Trichostrongylus colubriformis* in the Human Appendix Report of a Case in Louisiana.—*Jl Lab & Clin Med* 1938 Oct. Vol. 24 No 1 pp 15-17 With 1 fig

The first report of *Trichostrongylus colubriformis* in man in America though it is common in ovines there

In an appendix removed for recurrent abdominal pain there were found in the lumen two male *Enterobius vermicularis* and one male *T. colubriformis* identified by FAUST To the naked eye the appendix was normal in the wall were patches of plasma cells and some macrophages it is not believed that the parasites were concerned in the symptoms. No ova were found in the faeces though the girl had an eosinophilia of 7 per cent about a month later C L

GRAM (Eloise B.) & REARDON (Lucy) Studies on Oxyuriasis. XII Epidemiological Findings in Washington, D C.—*Amer Jl Hyg* 1939 Jan Vol. 29 No 1 Sect. D pp 17-24 With 2 figs (1 map)

Of 2,097 persons examined by the N I H swab in or near Washington 41 per cent were found infected by threadworms

This paper considers 1,362 persons from institutions already reported upon in the series as well as 735 from the general population and as regards the latter group the writers consider that it represents fairly well as to social and economic status a cross section of the white population of Washington. Those found infected were most numerous in but far from being confined to the older comparatively congested residential sections of the city round the Capitol While the numbers are felt not to be sufficiently large to constitute a fair sample of the whole population they do at least show that infection with *Enterobius vermicularis* is a public health problem of considerable importance without restriction of sex race age, social-economic status or place of residence. C L

NOLAN (M O.) & REARDON (Lucy) Studies on Oxyuriasis. XX. The Distribution of the Ova of *Enterobius vermicularis* in Household Dust.—*Jl Parasitology* 1939 Apr Vol. 25 No 2 pp 173-177

Ova of *Enterobius vermicularis* were found in dust collected at all levels in all of the rooms of 7 houses occupied by one or more persons heavily infected with pinworms. The ova in part at least, must have been carried by air currents. Infection by inhalation is therefore theoretically possible and should be considered in the prophylaxis and therapy of oxyuriasis.

The eggs were collected by passing a camel hair brush moistened with water over the surface being investigated it had been passed through a perforated rubber stopper fitting a test tube and was thus transported to the laboratory Here the brush was dipped gently into decinormal caustic soda solution in a deep well slide and examined. Of the 241 dust samples collected from these 7 houses threadworm ova were found in 221 (91.7 per cent.) and in largest numbers in bedrooms. About a quarter of the eggs were too disintegrated for the stage of development to be stated of the rest more than three-quarters contained fully formed embryos, and though only 15 of them were

mobile when examined, yet their appearance suggested that half the rest were viable or only just dead. This was confirmed by incubating 24 of these eggs selected at random, in "digestive juice" at 37°C. when 14 had hatched partly or completely and another was active but had not hatched. The sites of the ova were many including bedding, tub, basin, toilet seat, and children's toys and outer play garments, and a trichuris egg was collected from the middle moulding of a bedroom door. [Presumably it too was airborne.] C. L.

HAMBURGER (Franz) Die Oxyurenneurose [Neurosis from Thread worms].—*Med Klin* 1939 Mar 24 Vol. 35 No. 12 (1787) pp. 369-370

Threadworm infection is usually harmless and to subject a child to measures for prevention which continually draw attention to the condition is to produce neurosis in both mother and child. The best procedure is to treat pruritus if present by a simple ointment, and to give garlic enemata and small doses of santonin but the latter treatments should not be continued for more than a day or two at a time. C. L.

WRIGHT (Willard H.) BOZICEVICH (John) & GORDON (Leon S.) Studies on Oxyuriasis. VII. Clinical Improvement following Treatment with Single Doses of Tetrachlorethylene.—*Amer J Trop Med* 1939 Sept. Vol. 18 No. 5 pp. 609-617

Among 50 boys of school age treated for oxyuriasis with single doses of tetrachlorethylene clinical improvement occurred in a number of cases as indicated by gains in weight, amelioration of certain symptoms and changes for the better in social attitude and scholastic standing.

The need for detailed studies concerning the clinical features of oxyuriasis is pointed out, since in this regard there appears to be a dearth of reliable data based on adequate surveys of a sufficient number of cases.

C. L.

HALL (Maurice C.) Three Parasites which Habitually Surmount our Sanitary Barriers.—*Livro Jubilar do Prof. L. Tréassos*. Rio de Janeiro 1938 pp. 195-211 [16 refs.]

The three parasites are *Trichinella spiralis*, *Enterobius vermicularis* and *Entamoeba histolytica*. So long as this trio can override the barriers we have set up for our protection, so long will it be evident that we do not yet have the requisite knowledge, ability or desire to protect ourselves from these pathogens.

Trichinosis.—Recent autopsies on a large scale have shown that in man the incidence of this infection in the United States lies between 10 and 20 per cent. that in swine it is not less than it was 40 years ago that man gets his infection from swine and that swine get theirs from other swine through giving them to eat raw material which in a poorer country would be cooked and eaten by man. Press warnings have proved useless: people will not sterilize pork by proper cooking and it is felt that the most likely means of betterment is through the packers (the purchasers of swine-growers' products) by an insistence that what they buy shall meet certain reasonable specifications. The

present state of affairs has essentially come about as the result of political and economic conditions based on international trade

Enterobius infection—Stress is laid on its prevalence in Washington amounting to 35 per cent of the general population as disclosed by anal scraping (done often on one occasion only by the N I H swab) and on the way in which the eggs when dried and no longer sticky will fall off the body, sift through clothing and be widely dropped on floors chairs carpets, at home and in streets churches playgrounds shops and elsewhere and will even be carried by air As they are not except by accident faecal constituents they are not prevented from spreading by the ordinary sanitary measures which limit ordinary intestinal parasites Treatment is likely to be the only effective means of combat and some work indicates that the use of a suitable anthelmintic 3 times a day over a period of 10 days will do much to defeat pinworms [see WRIGHT and BRADY this *Bulletin* 1939 Vol. 36 p 329] while the thorough use of a vacuum cleaner will perhaps be of considerable value

Entamoeba histolytica apparently surmounts sanitary barriers by a residuum of cysts remaining about the anus and being passed on by means of food handlers, swimming pools underwear bedding towels washrags and other objects. C L

HOOD (Marion) & OLSON (S W) Trichinosis in the Chicago Area.—*Amer Jl Hyg* 1939 Mar Vol 29 No 2 Sect D pp. 51-56 [19 refs]

Numerous publications indicate that the average incidence of trichinosis in the United States is approximately 13 per cent As no survey had been made in the Chicago area a series of 428 autopsy cases was studied

The material was obtained from unselected autopsies performed at several Chicago hospitals When both the digestion and pressed muscle methods were employed 16 per cent. of the diaphragms were found infected with the larvae of *Trichinella spiralis* These results are in accord with those found in surveys from other localities.

Of the 428 samples investigated 48 were from infants under 1 year of age Four (8.3 per cent.) of these contained trichina larvae

A method is suggested for a more rapid means of investigation in surveys for *Trichinella spiralis* C L

BOZICEVICH (John) Studies on Trichinosis XII The Preparation and Use of an Improved Trichina Antigen—*Public Health Rep* 1938 Dec. 2. Vol 53 No 48 pp 2130-2138 With 1 fig [Summary appears also in *Bulletin of Hygiene*]

The antigens which have been used have been prepared in various ways and probably are not of equal value. In the method described the *Trichinella* larvae prepared from digested infected meat are obtained with a minimum of debris and special care is taken to obtain them free from proteins The dried ground larvae are extracted with neutral 0.85 per cent. solution of sodium chloride No preservative is used in making the antigen but the vials are subjected to fractional sterilization It shows no loss of titre after six months even in sunlight at room temperature By means of precipitin and intradermal tests it was found superior to antigens prepared by other methods It was used for both precipitin and intradermal tests in an outbreak of 44 cases of trichiniasis and all the patients ultimately reacted positively.

to both tests. A method is described and recommended for performing the intradermal test and a procedure for measuring the reaction.

W G Savage

McNAUGHT (James B) The Diagnosis of Trichinosis.—*Amer J. Trop Med* 1939 Mar Vol 19 No 2 pp 181-192. With 5 figs [15 refs]

1 While morbidity statistics indicate that less than 3 people per 100 000 suffer from trichinosis annually the examination of cadavers proves that about 400 people per 100 000 are infected annually. It is therefore evident that physicians are not so skilful in recognising this infection as they are in diagnosing many other diseases.

2 The number of parasites ingested, the physical condition of the patient and the specific tissues most heavily invaded must play important rôles in the severity of trichinosis infection.

3 Attention is called to the splinter hemorrhages seen beneath the nails of patients during the migrating stage of trichinosis.

4 The finding of parasites in blood, bile stool, cerebrospinal fluid or biopsy is possible but the diagnosis may be made without recovering the parasites from the patient. Eosinophilia is the most useful clue. Skin and precipitin tests establish that the eosinophilia is due to trichinella invasion rather than to some other cause.

A reproduced photograph shows two finger nails with "splinter hemorrhages" which Drs BIGGS and BRUCK informed McNaught they have found under finger and toe nails in 60 to 70 per cent of persons while in the active stage of infection, a sign which they believe to have been unrecorded hitherto. A photograph of a squash preparation from a sausage shows how heavily these may be infected.

Photograph showing splinter hemorrhages beneath the nails of a patient with trichinosis.

VAN SOMEREN (Vernon D) The Bone Marrow in Trichinosis of the Rat.—*Jl Helminthology* 1939 Jan. Vol. 17 No 1 pp 13-20
With 8 figs on 2 plates.

Eight rats were each infected with 500-600 encysted *Trichinella* larvae. The changes in the marrow of the femur are reported at from 13 to 45 days after the infection (that is during the acute stage) and at 90 days (that is after recovery).

After such a dose of larvae the percentage of eosinophils in the blood rose to 70 or 80 two to four days after infection. It then fell to 45 to 50 for a considerable time (the rat normal is 30 to 35). From one femur the red marrow which it normally contains was spread as a smear, the other femur after decalcification was cut in sections 10 μ thick. The normal bone marrow of the rat is described. In two controls blood counts were made frequently and in all infected rats immediately before killing them. In the acute stage there is functional myeloid hyperplasia at the periphery and ends of the marrow; the percentage of normal mature marrow neutrophils is lowered, they probably being liberated into the blood; basophils and basophile myelocytes are fewer; formed eosinophils of the ring nuclear type are generally more numerous than myelocytes. The differential blood and marrow counts varied in each rat.

After recovery there were two different pictures—first a persistent low grade blood eosinophilia with the marrow still showing the effect of stimulation; second a blood count with abnormally high neutrophils and normal eosinophil count; a marrow hyperplastic but with the ratio of mature neutrophils to myelocytes inverted, and in the smear a great number of nuclear ring forms. The changes are not directly related to the severity of the muscle infection. C L

VAN SOMEREN (Vernon D) The Treatment of Trichinosis. A Review of Methods.—*Brit Med Jl* 1939 Feb 25 pp 376-381
[67 refs.]

The clinical and symptomatic treatment of trichinosis is briefly discussed and measures for the destruction of the parasite in the host are reviewed. Radium irradiation and catharsis appear to be of no practical value. The use of convalescent antiserum to control the toxic features of the disease should be tried if such serum could be made readily available.

Most chemotherapeutic measures involving the use of anthelmintics, antiseptics, disinfectants and related substances, organic arsenicals and similar substances and certain miscellaneous drugs have been shown experimentally to be of no value and perhaps dangerous. There is experimental evidence, however, that the subcutaneous injection in olive oil or gum arabic of a suspension of the commercial thymol preparation carvasept or the oral administration of butolan (Bayer) (carbamic acid ester of *p*-oxy-diphenyl methane) is lethal to a certain proportion of reproductive adults in rats and their use results in a lessening in severity of the muscle invasion. A clinical trial of butolan should be made.

Excellent results have followed the intravenous administration of 5 c.cm. of gluco-calcium (Lilly) during the hitherto intractable acute migratory phase; this form of therapy should be given further clinical and experimental trials.

Experiments with rats, rabbits, and cats have shown that calcification after encystment may be considerably hastened by the administration of some vitamin D-containing substance supplemented by a supply of calcium in the form of a bland organic salt, thus protecting the host from toxic effects following encystment. Though a warning has been given

that this treatment may result in a dangerous metastatic calcification of other organs, a further judicious clinical trial should be made. It should be noted, however that this treatment is of no value before encystment of the larvae—that is, before four to five weeks have elapsed after infection.

MACIT ARIF Un cas de distomatose humaine à *Fasciola hepatica* et trois cas d'anguilluloses à Zonguldak (Turquie) [One Infection with *F. hepatica* and Three with *Strongyloides* at Zonguldak, Turkey]—*Rev Méd et Hyg Trop* 1938. Nov-Dec. Vol 30 No 6 pp 346-350

Strongyloides it is said, has not hitherto been reported from Turkey while *F. hepatica* has been recorded twice before in man

C L.

FOSTER (A O) & JOHNSON (C M.) An Explanation for the Occurrence of *Capillaria hepatica* Ova in Human Faeces suggested by the Finding of Three New Hosts used as Food.—*Trans Roy Soc Trop Med & Hyg* 1939 Feb 28 Vol 32 No 3 pp 639-644 With 2 figs [25 refs.]

When *Capillaria* eggs are found in the faeces of man, they have been ingested with his food.

Capillaria hepatica is a tissue parasite of the liver usually of that of a rodent, the eggs are laid in the tissue of that organ and do not reach the exterior while the host is alive. After the host's death they are either freed by the decomposition of the host's body and may then be distributed by flies or some other animal eats the infected liver. On one occasion they have actually parasitized man [MACARTHUR, this Bulletin 1924 Vol 21 p 963] but ordinarily the finding of eggs in man's stool has been attributed to their having been swallowed, man having eaten rat or dog for the dog too is an efficient host. But several cases have been reported from Panama and those who live there do not eat rat or dog but they do eat the white-tipped peccary *Tayassu pecari spiridens* the red spider monkey *Ateles geoffroyi* and the white faced monkey *Cebus capucinus imitator*—and in all of these animals the writers found *C. hepatica*. Moreover these eggs are not visibly altered on cooking and on feeding infected, boiled peccary liver to monkeys and cats the eggs were found in these animals' faeces. And the Panamanians customarily cook their meats very thoroughly

C L.

VENOMS AND ANTIVENENES

Précis of Abstracts in this Section

BORMANN (p 853) describes some of the commoner snakes of the Cameroons and the effects of their venoms. PAULI MAGNUS (p 853) comments on this and records a case showing the rapidly toxic effect of bites by *Naja melanoleuca* and the need for the early administration of antivenene. MARTIN DEL CAMPO (p 853) reports that he found in the north-west of Guatemala two species of *Bothrops* new to Mexico.

Madame PHISALEX (p 854) calls attention to the fact already well known that the yellow venom of *Isoperon aspis* is necrosing and neurotoxic in action but some specimens produce a colourless venom

South Africa. Their Unit is ten times the amount needed to neutralize one m.l.d. for mice and is contained in a fixed volume. They suggest that commercial antivenenes be tested against this standard and the dose regulated accordingly. IPSEN (p. 861) remarks that standardization of antivenenes demands preliminary standardization of venoms and since different individuals of the same species produce venom of different strengths (see VELLARD above) and even the same individual does not produce at all times the same strength venom as many samples as possible should be collected to obtain an average. For assaying antivenenes he finds the intravenous test in mice (Zagreb method) the most satisfactory. BOQUET (p. 862) adds further support to Calmette's view that antivenenes are not so specific as most people are inclined to believe. Apart from the specific elements there are group elements (paraspecific the author calls them) common to several venoms and this fact should be borne in mind when preparing and employing antivenenes.

D'ARREU (p. 862) reports a case of recovery after a bite by a krait. It is probable that the patient did not receive the full dose of venom the onset of symptoms was delayed for some hours and antivenene was not administered till 23 hours had elapsed. From description of a case of *Diploides typus* bite (Green Tree snake) in the Cameroons, reported by KRAEZE (p. 863) the venom resembles that of the *Lachesis* genus of South America. In the instance reported, the symptoms were mainly local with considerable resultant anaemia, but recovery ensued without specific antivenene, though 10 cc. of anti-cobra serum were given. ALLEN (p. 863) points out the advantages of the Jackson method of treatment of snake-bite—incision followed by suction—over local chemical injections.

Scorpions.—SERGENT (p. 864) describes and illustrates the scorpions of northern Africa and details cases of scorpion sting in Algeria where deaths from this cause are not very rare. He points out the value of antivenene when given early and in fairly large doses. KENT & STAHNKE (p. 865) writing of the species found in Arizona note the seriousness of stings by *Centruroides sculpturatus* which in children particularly are not infrequently fatal after convulsive attacks and signs of respiratory distress. Attention is called by VARELA (p. 865) to the effect of calcium chloride in cases of stinging by another species of the same genus, *Centruroides limpidus* but from his account it would appear to do little more than delay death in animals on which this treatment was tested. DE MAGALHÃES (p. 866) gives a general account of the common scorpions of Minas Geraes and the symptoms produced by their venoms. In a further paper he describes more fully their neurotoxic action.

Whereas (see above CÉSARI) certain snake venoms have their toxicity attenuated by addition of formaldehyde without reduction of their antigenicity in the case of scorpion venom VARELA & SÁNCHEZ POSADA (p. 866) show that both properties are destroyed thereby.

FINLAYSON (p. 867) relates his researches on the venom of *Latrodectus indistinctus* its thermostability the effects on it of chemicals such as gold chloride potassium permanganate and formalin and the haemolytic properties of the venom itself and of an emulsion of the dried insect. With his co-workers he shows (p. 867) that the venom has a depressant action on heart muscle. It probably contains more than one toxic principle and some of its effects may be due to the release of a histamine-like substance in the tissues. MACKINNON (p. 868)

VOX KLOBUKITZKY (D) & HOSIO (P) Biochemische Studien ueber die Gifte der Schlangengattung Bothrops. VI. Mitteilung Kurzer Bericht ueber verschiedene in den Jahren 1936-37 gewonnene Versuchsergebnisse [Biochemical Studies of the Venom of Bothrops. VI Short Report on Various Findings during 1936-37]—*Arch f Experim Path u Pharm* 1939 May 10 Vol 192 No 3 pp 71-75 With 1 fig

PRUSALTY (Marie) Le venin blanc des vipères du département du Gers est depourvu de pouvoir vaccinant [The Colourless Venom of the Vipers of Gers has no Vaccinating Power]—*C R Acad Sci* 1939 Apr 17 Vol 208 No 16 pp. 1252-1254

Specimens of *Vipera aspis* from certain districts had previously been found to provide colourless venom instead of the usual yellow and this is more neurotoxic and less necrosing than the yellow and is completely neutralized by anti viper serum. Yellow viper venom loses its antigen and becomes more toxic on account of this loss, when subjected to short wave radiations for 30 minutes.

Tests of the colourless venom (which has maximum toxicity in summer) were made on mice. The venom was divided into two portions, one of which was heated to 75 C. for 15 minutes to destroy toxicity. This was used for vaccination and 48 hours afterwards rather more than 1 ml d. was injected into each animal. In all cases, with venom collected in spring, summer and autumn, no evidence of protection was seen.

This colourless venom therefore has no protective power. It provokes neither necrotic nor haemorrhagic reaction but is simplified practically to a neurotoxin. C IV

PEREZ (Francesco) Ulteriori ricerche sugli ofidi velenosi dell' A.O.L. [Recent Work on the Poisonous Snakes of Italian East Africa.]—*Boll Istituto Sieroterap Milanese* 1939 Jan Vol 18 No 1 pp 1-8 With 4 figs. on 2 plates [16 refs.] French summary (7 lines)

The author studied the venom of *Atractaspis microlepidota* Magretti obtained from the dried gland, which is a long delicate structure (up to 30 cm. in length) with an ampulla close to the base of the fang. The venom has a powerful toxic action, about twice as strong as that of *Vipera ammodytes* and may be lethal to man, especially if introduced into a vein by the long slender fangs. In animals respiration is paralysed, the venom being rich in neurotoxin and poor in enzymes. Haemolysis and coagulation of citrated plasma are not produced *in vitro*.

Two monovalent sera neutralize this venom, that prepared against *V. nigricollis* and that against *V. ammodytes*. Polyvalent antivenene contains the former and it is unnecessary to prepare serum directly against *A. microlepidota*.

Psemmophis sibilans was also studied and although its venom possesses neurotoxic properties, the small quantities available in the glands and smallness of the fangs, set far back, render this snake comparatively harmless to man. C IV

obtained in a homogeneous or crystalline state it can be concentrated tenfold. The authors believe that the proteolytic and coagulating activities are due to the same protein, which, when highly purified shows the properties of an albumin.

The neurotoxic principle can be obtained pure and is the first proteinic toxin which has so far been crystallized. It contains the whole neurotoxic and haemolytic activities of the venom, which have hitherto been attributed to two different substances. The authors name this substance crotoxin. It contains 4.0 per cent. of sulphur and the molecular proportion of methionine to cystine is exactly 1 : 6

C IV

GHOSH (B. N.) & DE (S. S.) Proteins of Rattlesnake Venom. [Correspondence]—*Nature*. 1939 Mar 4 Vol. 143 No 3616 pp 390-391

By dissolving 100 mgm. of venom of *Crotalus terrificus* in 10 cc. water adjusting to pH 7.0-7.2, saturating with sodium chloride overnight at 6°C., separating the precipitate by centrifugation, and washing again in saturated sodium chloride the authors found the precipitate to contain 8-10 per cent. of the total haemolytic activity and only 2-2.5 per cent. of the total neurotoxic activity of the original venom. This proportion of 4 : 1 between the two is much higher than in the original venom and the two activities are therefore due to two different substances. The crystalline substance obtained by SLOTTA and FRAENKEL-COVAT [see above] was therefore a mixture of at least two different proteins.

Similarly the haemolysin and neurotoxin of *Naja naja* venom have been separated

C IV

VELLARD (J.) Propriétés du venin des principales espèces de serpents du Venezuela [The Properties of the Venom of the Principal Snakes of Venezuela.]—*Ann Inst Pasteur* 1938 May Vol 60 No. 5 pp 511-548

Following his previous work in which he described differences existing between the venoms of specimens of *Bothrops atrox* from different parts of South America [this Bulletin 1937 Vol. 34 p 656] the author has made a study of *Crotalus terrificus*, *Lachesis muta*, *Bothrops atrox*, *Bothrops nasuta* and *Elaps lemniscatus* in the same way. The methods employed were similar to those used previously and the properties of the venoms under the headings of coagulant, anti-coagulant, haemolytic, anti-haemolytic, anti-complementary, proteolytic and necrosing were examined separately *in vitro* and *in vivo*. Determination of the susceptibility of the principal laboratory animals was made.

The venoms of *L. muta* and *B. nasuta* were constant in all the specimens examined, such differences as were found were entirely quantitative and could be accounted for by individual variations. The results with the venom of *E. lemniscatus* though indicating that differences were not appreciable, could not be regarded as conclusive on account of the small quantities available for testing. The venoms of *C. terrificus* and *B. atrox* however showed clear differences between the specimens from different parts.

toxic factor and the spreading factor are neutralized by specific antiserum *in vitro* as well as *in vivo*

Little or no spreading factor was found in toad venom though this is extremely poisonous for both the circulatory and the nervous system. Extracts of non poisonous insects, e.g. crickets grasshoppers dragon flies etc. did not contain it, but it was found in extracts of bees, wasps mosquitoes and especially spiders

It would appear in the case of snakes, that a relationship exists between the local tissue action and the spreading factor content and the author likens the rattlesnake venom, containing the factor to *Clostridium welchii* and the toad venom to *Cl. tetani*

An interesting point is that extracts of the cells of the poison gland of the rattlesnake contain very little toxin or spreading factor but that both are present in the secretion of the gland [The work of CASTELLANI this Bulletin 1839 Vol 38 p 567 may have some bearing on this point] C II

FAYILLI (G) I fattori di diffusione o ro natura meccanismo d'azione significato [Spreading Factors their Nature, Mode of Action and Significance].—*Boll Istituto Sieroterap Milanese* 1838 Nov Vol 17 No 11 pp 711-714 German summary (5 lines)

A physiological solution injected into the skin behaves like liquid dropped on writing paper if it contains the spreading factor it behaves like liquid dropped on blotting paper

Tumours are especially rich in spreading factor and it is contained in various organs. The intensely rapid action of snake venom is due to it. The diffusion of scorpion venom is so rapid that if injected into the skin in a dilution of 1 in 100 000 no bleb is formed and dispersion is immediate

Antivenene neutralizes but in an incomplete manner the spreading factor of the homologous venom. Anti-viper serum, however does not neutralize the factor in crutaline or in cobra venom. The spreading factor is antigenic and specific. A spreading factor is present in certain micro-organisms (staphylococci streptococci pneumococci) and in the exotoxins of the gas gangrene group but cannot be identified with the endo- or exotoxins. The existence of a single uniform factor in venoms cannot be substantiated. The factors have been considered to be proteins but the author has succeeded in partially separating them from the proteins in the case of the testicular factor. They resist drying

The factors act only on collagenous connective tissue and probably therefore on the capillaries and lymphatics, and exert an influence on the exchange between connective tissue and the capillaries and lymphatics C II

VELLARD (Jehan) Variations de la résistance globulaire *in vivo* sous l'influence des venins de serpent. [Variations in Red Cell Resistance under the Influence of Venom *in vivo*].—*C. R. Acad Sci* 1839 Feb 27 Vol 208 No 9 pp 669-671

A distinction must be made between resistance to venom haemolysins and resistance to mechanical action or hypotonic solutions. Coagulant and non-coagulant venoms have different effects.

CÉSARI (E.) & BOQUET (Paul) Sur le mécanisme de la détoxication du venin de *Vipera aspis* par l'aldéhyde formique. [The Mechanism of the Detoxication of the Venom of *V. aspis* by Formaldehyde.]—*C R Soc Biol* 1939 Vol. 130 No. 1 pp. 19-23

It has been shown [this *Bulletin* 1931 Vol. 28 p. 549 1934 Vol. 31 p. 103] that the addition of 3 to 10 parts per thousand of formaldehyde to snake venom causes, in a few weeks, attenuation of the toxic action without alteration of antigenic power. The authors have studied this effect with reference to the components of the venom of *V. aspis*. They added 2, 4 and 6 parts per 1 000 of 40 per cent. formaldehyde to solutions of 10 mgm. venom per cc. physiological saline. This mixture was incubated at 37°C. and tested at intervals on rabbits, guinea-pigs, citrated plasma and washed horse erythrocytes in the presence of normal horse serum. Results were compared with those obtained with pure venom.

Toxicity was attenuated very rapidly in 24-48 hours, especially with 6 per 1 000 formaldehyde, when tested by intravenous injection in rabbits, more slowly when tested subcutaneously in mice and guinea-pigs (2 weeks). Coagulation was completely inhibited at 48 hours with 6 per 1 000 and at 72 hours with 4 per 1 000. Haemolytic power however was only slightly affected after 15 days by 6 per 1 000. The action of formaldehyde is therefore selective. C IV

BOQUET (Paul) Sur le rôle du cuivre dans l'atténuation du venin de vipère (*Vipera aspis*) par l'eau oxygénée. [The Role of Copper in the Attenuation of the Venom of *V. aspis* by Hydrogen Peroxide.]—*C R Acad Sci* 1939 Mar. 6 Vol. 203, No. 10 pp. 770-772

A solution of viperine venom (1 in 500) in distilled water mixed with an equal quantity of hydrogen peroxide (100 volumes diluted 1/100, 1/200 etc.) and kept for 20 hours at 37°C. is harmless to rabbits in 5 times the normal lethal dose. The hydrogen peroxide was prepared with the same distilled water in which traces of copper from the still were found. On substituting water distilled from a glass still there was no attenuation of the venom but when 1 mgm. per litre of copper sulphate was added, attenuation was again produced. No attenuation was found with copper in the absence of hydrogen peroxide.

The copper probably acts as a catalyst in fixing the oxygen and the experiment shows with what care reagents must be prepared.

C IV

BOQUET (Paul) Sur le rôle de quantités infinitésimales de cuivre dans l'atténuation du venin de vipère (*Vipera aspis*) par l'eau oxygénée. [The Role of Small Quantities of Copper in the Attenuation of the Venom of *Vipera aspis*.]—*C R. Soc Biol* 1939 Vol. 131 No. 15 pp. 7-10

In continuation of the experiments in the preceding paper the author found that when a solution of the venom was mixed with hydrogen peroxide in different amounts and with a solution of 1 mgm. to the litre of copper sulphate the toxicity decreased in proportion to the concentration of H_2O_2 , and to the length of time of contact with the reagents. Control mixtures without copper remained toxic for much

The author advises that sera should be marked according to the venoms used in preparation, since there are well marked geographical localizations of the various species in Europe. He suggests that the mouse intravenous test should be used rather than tests on rabbits.

C IV

BOULET (Paul) Immunité antivenimeuse spécifique et paraspécifique. [Specific and Paraspécific Immunity against Venoms.]—*Rev d'Immunologie* Paris. 1938. Juh. Vol 4 No. 4 pp. 359-370 [26 refs.]

Recent researches have supported the opinion expressed by CALMETTE that the specific nature of antivenenes is not so strict as was thought. CÉSARI and the author have shown that a bivalent serum prepared against *B arictans* and *S haemachates* (neither of which contains a coagulant principle) can neutralize *in vivo* and *in vitro* the coagulating effect of the venoms of *L russells*, *C cornutus* and *L aspis* but has almost no action against the coagulating principle of *C terrificus* and *B atrox*. It also protects against the anticoagulating principles of *B arictans*, *S haemachates*, *N flava* and *N tripudians*. The venom of *L lebetinus* of Africa is better neutralized by anticobra than ant viper serum.

The paraspecific action of serum seems to result from antibodies capable of combining with group antigens, but, as VELLARD [see this Bulletin 1937 Vol 34 p. 656] has pointed out, members of the same species but from different districts elaborate different antigens. In spite of this however members of different species elaborate certain antigens which are identical, and which have strictly specialized properties. These common antigens are the group antigens, and should be taken into account in the preparation of antivenenes [this Bulletin 1937 Vol 34 pp. 641-646] by making use of those venoms which contain the antigens most commonly found in the district in which the serum is to be used.

The author makes a plea for uniformity in methods of titration and systems of units. A useful table of the actions of common venoms is given.

C IV

D'ARREU (A. R.) Poisoning by Bite from *Bungarus caeruleus* with Recovery.—*Indian Med. Gaz.* 1939. Feb. Vol 74 No. 2, pp. 84-85.

The patient a juggler who used snakes in his acts but who could not distinguish between the poisonous and non-poisonous kinds, picked up what he later identified as a krait (*Bungarus caeruleus*) which bit him in the hypothenar eminence. He sucked the wound and ligatured his wrist. No effects were felt for some hours but 13 hours after the bite he was admitted to hospital with fully developed symptoms of colubrine venom poisoning. Anti-serum C (Pasteur Institute of Paris) labelled as specific against the venoms of *Naja* and *Bungarus* snakes was given intravenously about 23 hours after the bite (it was not available earlier). Cyanosis and respiratory paresis with salivation, indistinct speech ptosis paresis of the limbs diminished tendon reflexes (but no loss of tactile sensation) and great prostration were found, but there was no local reaction. Signs of pneumonic

consolidation appeared but rapidly cleared and the patient recovered slowly at first

The amount of venom available in the krait is about three lethal doses for man but possibly the thick epidermis of the palm of the hand prevented effective penetration by the small and fine fangs which are also in some instances not completely tubular and may thus permit escape of the venom. Recovery from the bite of the krait is rare C IV

KNABE (Kurt) Schlangenhiss eines Kamerunnegers durch grüne Baumschlange (*Dipholidus typus*) [The Bite of the Green Tree Snake (*Dipholidus typus*)]—*Arch f Schiff- u Trop-Hyg* 1939 Apr Vol. 43 No 4 pp 173-174

The symptoms in a native in the Cameroons bitten by this snake were swelling of the bitten hand and arm, pain vomiting rapid and weak pulse and headache. Bleeding continued for some days from an incision made at the site of the bite and haemorrhagic necrosis of the edges took place. Ecchymoses appeared in the mouth but no blood was found in the vomit or stool. Erythrocytes diminished to 2-6 millions and haemoglobin to 30 per cent.

Treatment was symptomatic but in the absence of specific antiserum 10 cc. anti-cobra serum was given. The patient was very ill for about a week when improvement started.

The effect of the venom is comparable with that of the South American snakes of the genus *Lachesis* and death results from vasomotor paralysis and haemorrhages in the internal organs due to lysis of the capillary walls by a toxic haemorrhagin. C IV

ALLEN (Frederick M) Mechanical Treatment of Venomous Bites and Wounds.—*Southern Med J* 1938. Dec. Vol. 31 No 12. pp 1248-1253 [14 refs]

The author states that all authorities are agreed as to the uselessness and actual harmfulness of the injection of permanganate and all other chemical solutions designed to destroy or neutralize venom. There is no method of occlusive ligation which affords the slightest protection or benefit against venom in animal experiments. Successive tight ligations and releases are effective if a rapidly absorbed poison such as strychnine is injected but are useless for snake venom which is usually absorbed slowly.

The Jackson treatment [see this *Bulletin* 1929 Vol. 26 p 273] consists in the use of a very lightly applied tourniquet just enough to obstruct the lymph circulation and not the free venous return. Under local anaesthesia a rather large crucial incision is made at the site of the fang marks, and a ring of smaller cross incisions about $\frac{1}{4}$ inch wide by $\frac{1}{4}$ inch deep is made round the advancing edge of the swelling. Suction over these with a special form of cup is employed to draw out large quantities of fluid, and the flow is further increased by the injection of several hundred cc of 1 per cent salt solution into the incisions. Suction is continued for half to one hour then repeated for 20 minutes hourly for 10 to 15 hours.

This treatment has been successful in experimental work with dogs and the fluid removed by the suction has been shown to be fatal to

The author advises that sera should be marked according to the venoms used in preparation since there are well marked geographical localizations of the various species in Europe. He suggests that the mouse intravenous test should be used rather than tests on rabbits.

C IV

ALLEN (Frederick M) Mechanical Treatment of Venomous Bites and Wounds—*Southern Med J* 1938 Dec Vol. 31 No 12. pp 1248-1253 [14 refs.]

The author states that all authorities are agreed as to the uselessness and actual harmfulness of the injection of permanganate and all other chemical solutions designed to destroy or neutralize venom. There is no method of occlusive ligation which affords the slightest protection or benefit against venom in animal experiments. Successive tight ligations and releases are effective if a rapidly absorbed poison such as strychnine is injected but are useless for snake venom which is usually absorbed slowly.

The Jackson treatment [see this *Bulletin* 1929 Vol. 26 p 273] consists in the use of a very lightly applied tourniquet just enough to obstruct the lymph circulation and not the free venous return. Under local anaesthesia a rather large crucial incision is made at the site of the fang marks and a ring of smaller cross incisions about $\frac{1}{4}$ inch wide by $\frac{1}{4}$ inch deep is made round the advancing edge of the swelling. Suction over these with a special form of cup is employed to draw out large quantities of fluid and the flow is further increased by the injection of several hundred cc of 1 per cent. salt solution into the incisions. Suction is continued for half to one hour then repeated for 20 minutes hourly for 10 to 15 hours.

This treatment has been successful in experimental work with dogs, and the fluid removed by the suction has been shown to be fatal to

other dogs. It is perhaps best adapted to the venoms with powerful local action.

This treatment is simple and should be used even if antivenene is available, and certainly if it is not. Excision is only useful if considerable in extent. Amputation may be necessary and the use of an occlusive tourniquet should be reserved for control of haemorrhage for gaining time preliminary to amputation or for use with local refrigeration, another method of gaining time.

The author considers that Jackson's method deserves a thorough trial in the tropics. C IV

SERGEANT (Etienne) Iconographie des scorpions de l'Afrique du Nord. [Iconography of North African Scorpions].—Arch. Inst. Pasteur d'Algérie 1938. Dec. Vol. 16. No. 4 pp. 513-522. With 5 coloured plates

The differentiation of species of scorpions by colour characteristics is of considerable importance and this cannot be effected by monochrome photographs. Illustrations in colour are therefore here reproduced of *Prioxurus australis* (adult and young) *P. liouvillei*, *Buthus occitanus* and *Heterometrus maurus* together with brief notes concerning toxicity and habitat. [The coloured plates are beautifully executed and reproduced] C IV

SERGEANT (Etienne) Venin de scorpion et sérum anti-scorpionique. [Scorpion Venom and Antivenene].—Arch. Inst. Pasteur d'Algérie 1938. Sept. Vol. 16. No. 3 pp. 257-278

The author gives the details of 12 cases of fatal scorpion sting in Algeria and Morocco. In Algeria the dangerous scorpion is *Prioxurus australis* in Morocco *P. liouvillei* and one person died from the sting of the usually harmless *Buthus occitanus*.

Serious symptoms do not usually appear until two hours after the sting. They consist of violent pain, vomiting, vertigo, profuse sweating and sensation of cold, cardiac weakness, dyspnoea, cyanosis and coma.

Serum is prepared from horses and donkeys, and should be given as soon as possible in doses of from 10 to 50 cc. for adults. [The dose advised for children is not given but in 8 children detailed it varied from 10 to 50 cc. These children all died. Does the rule that the smaller the animal the larger should be the dose hold good for scorpion antivenene?]

In 33 patients whose condition was regarded as desperate, 26 were saved by serum. In 8 in whom the serum was injected soon after the sting there were no deaths. In 68 with definite but not grave symptoms there were no deaths. At Bou Saâda in 1932-1934 when no serum was available there were 22 deaths. In 1936 and 1937 when serum was used there was 1 death in 32 stung. At El Kantara from 1929 to 1935 when serum was not available, there were 12 deaths. In 1936 and 1937 when serum was used, there were no deaths in 51 stung, 14 of whom had grave symptoms.

Animals immunized against *P. australis* are protected against other North African species [see also this Bulletin 1937 Vol. 34 p. 727]

PALLARY (Paul) Sur des scorpions de la Berbérie de la Syrie et du Congo. [Scorpions of Northern Africa, Syria and the Congo]—*Arch Inst Pasteur d'Algérie* 1938 Sept. Vol 16 No 3. pp 279-282.

KENT (Melvin L.) & STAHKE (Herbert L.) Effect and Treatment of Arizona Scorpion Stings—*Southwestern Med* 1939 Apr Vol 23 No 4 pp 120-121 124

More deaths have resulted from scorpion stings in Arizona since 1929 than from any other venomous animal. The effects of the stings of *Leiurus spinigerus*, *Hadrurus hirsutus* and *Centruroides sculpturatus* on rats were studied the two former being relatively harmless the last being fatal. In man the effects of the sting of *C. sculpturatus* are invariably more pronounced in children than in adults and are almost always fatal to those under 1 year of age. The child cries out with pain but there is little sign of the sting. Restlessness follows with rigidity of the abdominal muscles tonic contractions of arms and legs and salivation. Temperature may reach 104 F. Cyanosis and difficulty of respiration involuntary urination and defaecation may follow and death supervene apparently from exhaustion. If recovery takes place there is numbness at the site of the sting and possibly temporary uselessness of the limb.

In treatment barbiturates and bromides the latter in large doses are valuable but morphine should be used only with extreme caution and has not been found useful in the usual dosage. Atropine may be given for severe pulmonary oedema and compresses of fairly strong ammonium hydroxide solution are useful if applied within a few minutes of the sting. Results with scorpion serum are encouraging and the author believes that no death has occurred when it has been used. One case is quoted in which the serum produced dramatic improvement within a few minutes of intramuscular administration.

VARELA (Gerardo) El cloruro de calcio en la intoxicación por la toxina del alacrán de Guerrero (*Centruroides limpidus* Karsch) Calcium Chloride in Scorpion Poisoning]—*An. Escuela Nac. Ciencias Biol. Mexico* 1938 Oct.-Nov.-Dec. Vol. 1 No 1 pp 133-134 English summary (2 lines)

Mice of 18 to 20 gm. tolerate the injection of 0.0187 gm. calcium chloride and this dose was mixed with the m.l.d. (0.0028 gm.) of the toxin of *Centruroides limpidus* Karsch and injected. Death occurred in some of the animals but much less early than in the controls. Similarly mice given calcium chloride after the appearance of symptoms following the administration of the m.l.d. of scorpion venom died, but much later than the controls. In the treated animals death was delayed up to the following day controls died in about 30 minutes.

Calcium chloride may therefore be useful in the treatment of sublethal scorpion poisoning. [No figures are given.]

C IV

DE MAGALHÃES (Octavio) Scorpionism.—*Jl Trop Med & Hyg* 1938 Dec. 15 Vol. 41 No. 24 pp 393-399 With 1 chart & 1 fig

The common scorpions of Minas Geraes are *Tityus bahiensis* and *T. serrulatus*. The venom can be kept dry at 0 C. for eight months with the loss of only half to quarter of its value.

The author gives three general laws. 1 The poison is toxic to the nervous system. 2 An animal is only absolutely immune when its central nervous system is immune. 3 The poison affects principally the neurones united in centres. But in the poison there are also haemorrhagins leucocytolytins agglutinins and haemolysins. The symptoms exhibited depend upon the dose and its proportion to the weight of the patient the kind of scorpion and the time of the year toxicity being greater in August September and October than at other times. The resemblance of the symptoms to those of acute syringobulbia is emphasized. The long account of the symptomatology given should be read in the original.

In Brazil 6,668 cases of scorpion poisoning are reported of which 237 were fatal. The author mentions a local treatment with the juice of the leaves or tubercle of the dahlia, which has some neutralizing action but serotherapy is the only effective measure. The deaths in a series [numbers not given] were 1.81 per cent with serum treatment 42 per cent without.

C IV

DE MAGALHÃES (Octavio) The Scorpionic Syndrome.—*Jl Trop Med & Hyg* 1939 Jan 2, Vol 42, No 1 pp 1-5

The venom of specimens of the genus *Tityus* contains especially a neurotoxin which is the killing agent. The author emphasizes the action on the nervous system the characteristic effect of which is an alteration of the superficial sensibility to pain. Painful hyperaesthesiae may be confined to the area of the sting or may radiate along the limb affected and may be exceedingly violent. Numbness itching or pricking sensations may be felt.

The venom of the Brazilian species of *Tityus* has a distinct and constant action upon the neurones of the cerebral cortex of laboratory animals. In man generalized convulsions disturbances of speech delirium and certain states of aggressiveness also indicate an action on the cortical neurones of the frontal lobes. There is an action on the cerebellum and on the medulla oblongata. The author gives a long table comparing the symptoms of severe scorpionism with those of syringobulbia. The resemblance is close. Attention is drawn to the fact that scorpion venom is not primarily of a digestive nature as is the venom of the *Opilidia* in general.

BARROS (Evandro da Fonseca) Contribuição ao conhecimento de lesões nervosas centrais provocadas pelo eneno escorpionico [Lesions of the Central Nervous System due to Scorpion Venom].—*Mém Inst Biol Espírital Dias* Belo Horizonte 1937 Vol. 1 300 pp With 3 text figs & 125 figs on 66 plates [40 refs.]

VARELA (Gerardo) & SÁNCHEZ POSADA (Enrique) Anaponzonás del veneno del alacrán de Guerrero (*Centruroides limpidus* Karsch) [Detoxification of Scorpion Venom].—*An Escuela Nac Ciencias Biol* Mexico 1938 Oct.-Nov.-Dec Vol. 1 No 1 pp 135-137 English summary (8 lines)

The addition to scorpion venom of formaldehyde (40 per cent.) to a concentration of 4 per cent. renders it non-toxic to mice after 7 days at 37°C. and at the same time deprives it of antigenic properties. Treatment with equal quantity of sodium ricinoleate in a concentration of 1 in 500 does not detoxify the venom as it does that of

V. aspis Lugol's solution in a concentration of 1 in 10 detoxifies scorpion venom in 24 hours in the refrigerator but destroys the antigenic power

The authors therefore recognize a distinction between snake toxins and scorpion venom

C II

FINLAYSON (M. H.) Some Properties of the Venom and Arachnolysin of *L. indistinctus*—*South African Jl Med Sci* 1937 Oct Vol 2. No 4 pp 151-155

Four matters of research were carried out by the author and described in this all too brief paper —

1 The thermostability of the venom of *Latrodectus indistinctus* This was determined by heating the venom for 30 minutes at 50 55° 60 70 and 80°C and injecting it intravenously into mice for which the control m.l.d. was 0.05 mgm Heating to 50°C had little effect at 55°C the venom was weakened and at 60°C totally destroyed.

2. The action of certain chemicals on the venom The toxicity was removed by 0.01 per cent gold chloride or potassium permanganate or of 40 per cent formalin (? formic aldehyde formalin is the name usually given to 40 per cent solution of formaldehyde) Fractionation by means of CO₂ results in a more highly toxic insoluble and less toxic soluble fraction

3 The haemolytic properties of the venom. It was found not to haemolyse human or guineapig's corpuscles even when guineapig serum was added, but it would haemolyse rabbit cells readily sheep cells slightly only

4 The haemolytic properties of arachnolysin that is a solution of the dried body of the insect This differed in several respects from the venom It readily haemolysed human corpuscles and of the rabbit (in this resembling the venom) it would not affect sheep cells unless guineapig serum was added. As for guineapig red cells these were haemolysed by the arachnolysin but not if guineapig serum heated or unheated, was added [see also this *Bulletin* 1937 Vol 34 p 732]

SHAPIRO (H. A.) SAFEIKA (N.) & FINLAYSON (M. H.) Pharmacological Actions of the Venom of *Latrodectus indistinctus*—*South African Jl Med Sci* 1939 Apr Vol 4 Nos. 1 & 2. pp 10-17 With 8 figs.

Poisoning by the bite of *L. indistinctus* the Knoppie spider is far from uncommon in South Africa [see this *Bulletin* 1937 Vol 34 pp. 732-3] In this article the authors record the results of their experimental work with the venom on the heart respiration intestine and skin of frogs, rabbits and cats It was found to have a depressant effect on the cardiac musculature and since the effect is not abolished by atropine the action is probably directly on the muscle. These depressant cardiac effects are associated with rise in blood pressure which however sinks after 2-3 minutes and there is increase also in intestinal and skin volume suggesting that the crude venom contains more than one toxic principle Some of the effects may be due to a histamine-like substance released in the tissue (as in the case of cobra venom) though none such was detected. The action on respiration is also depressant and death is due to this combined effect on the respiratory and vascular systems.

MACKINNON (Juan E.) Accidentes poco conocidos producidos por picaduras de arañas Arafismo cutáneo-gangrenoso y hemolítico [Little-known symptoms in bites by *Latrodectus mactans*].—*Arch Uruguayos de Med Ciruj y Especialidades* 1938 Nov Vol 13 No 5 pp 575-580 (16 refs)

The symptoms usually resulting from bites by the Black Widow spider are of a neurotropic nature [see this *Bulletin* 1936 Vol 33 p 401 1937 Vol 34 p 728]. Four cases are recorded here in three of which there was local necrosis and a gangrenous condition produced, in one with jaundice and in the fourth (third in the order described) marked systematic disturbance with haematuria, delirium coma and death in 36 hours this was a boy of 11 years bitten in the right subclavicular region by a spider which was found under his shirt

H H S

SARTH (Donn) & DAMOUR (Fred E.) Black Widow Antivenin Production in Rabbits.—*Proc Soc Experim Biol & Med* 1939 Apr Vol 40 No 4 pp 686-687

Antiserum against the Black Widow spider is usually prepared in the sheep and requires about 3,000 spiders for each animal. Loss of a sheep is therefore a serious matter. The authors attempted the production in rabbits. The venom glands were removed and macerated in saline debris was filtered off through cotton and the rabbits, of about 4 kgm. were immunized by subcutaneous injections on alternate days for the first 2 weeks one quarter of the venom of one spider was given for the next 2 weeks one spider for the next 2 weeks two spiders and for the last 5 weeks eight spiders at each injection.

Serum at the end of the 5th week showed little or no neutralizing power but after 11 weeks the results compared reasonably well with those of sheep serum. This finding may be important in the commercial production of antivenene where only small amounts of readily available serum are desired.

ASCONA (H L.) Histología de la glándula venenosa de *Cryptidromus bryeri* Becker [Histology of the Poison Gland of *Cryptidromus bryeri* Becker].—*An Escuda Nac Ciencias Biol Mexico* 1938 Oct-Nov Dec Vol 1 No 1 pp 107-112. With 5 figs on 3 plates. English summary (4 lines)

The author describes the anatomy and histology of the spider in considerable detail. There are two types of cells concerned in the production of venom. The first distributed over the membranous wall, consists of cells of about 60 μ in diameter which contain dark granules and glycogen. The cells of the second type distributed on the fibrous trabeculae which extend inwards from the wall, are from 120 to 130 μ in diameter. Nuclei in this type are either absent or pyknotic the cells are pyriform and contain the substance which constitutes the principal part of the venom together with mucin. Some of these cells are apparently in a state of rest others are disintegrating.

The venom of the spider is a mixture of the products of the two types, the first secreting its poison the second disintegrating to produce it.

SACCHI (P) Immunité active chez le lapin avec le venin des abeilles
 [Active Immunity in Rabbits against Bee Venom.]—*Boll. Sezione
 Ital. Soc. Interna. di Microbiologia* Milan, 1938. Oct Vol 10
 No 10 pp 211-213

Intravenous injection of Apitoxin Smit a solution of the venom of 1 000 bees in 100 cc. saline solution, into mice shows that it possesses paralyzing and haemolytic actions with the production of methaemoglobin. Intradermally it produces necrosis.

Eight rabbits were given 0.2 cc. of this venom subcutaneously and in the same place on alternate days during 20 days. Fifteen days after the last injection they with 6 normal controls were given minimal haemolyzing and necrosing doses and the flocculation test of Ramon was applied. The results of these three tests showed that antitoxic immunity to the extent of about 25 I.U. per cc. of serum had developed in the injected animals and none was found in the controls.

MISCELLANEOUS

BARDSWELL (A. D.) Tuberculosis in Cyprus (Final Report).—*Tubercle* 1938 Dec Vol. 20 No 3 pp 97-113 With 2 maps (1 folding) & 1 fig. 1939 Jan Vol. 20 No 4 pp 165-193 With 11 figs & 15 charts. (Summary appears also in *Bulletin of Hygiene*)

This is a report on the second and final year's work undertaken by the late Dr Bardswell and on account of the intelligent and careful use of the available methods of investigation provides a very complete confirmation of the opinions expressed in his first report [see *Bull. of Hyg.* 1939 Vol. 14 p 130 this *Bulletin* 1939 Vol. 36 p 342].

An intensive survey was made of the town and district of Larnaca comprising a population of 42 000. The whole school population was tested with tuberculin and positive reactors were followed up into their homes to find the person responsible for the infection. An enquiry was made into every known case of tuberculosis since 1931. Contacts were examined and a systematic study of the death registers was made. As the routine X-ray examination of large numbers of the general population was impossible it would be difficult to suggest more effective measures than were taken.

The many findings cannot be abstracted in full, but the principal conclusions are that tuberculosis is not so common as was thought (the incidence rate in the Larnaca district is about 3 per 1 000 of the population the average death rate 0.69) that it is essentially a disease of families that the Cypriots show high resistance to infection and to the spread of definite disease with chronic fibrous reaction rather than acute caseation and that bovine disease does not occur. It seems probable that some degree of inherited resistance is present and that this is aided by the climate and certain common habits such as that of sleeping out of doors in the summer. There is some experimental evidence that the virulence of the tubercle bacilli is normal.

The standard of living is low but there is no correlation between poverty and tuberculosis incidence and malnutrition is not an important factor. Malaria plays only a small part in the incidence of

tuberculosis. Contact is most effective where the patient (as is usual) sleeps in the same room as the other members of the family but even under these conditions may not produce infection if the beds are far apart. Sleeping away from contacts, even though using the same day time living accommodation greatly decreases the chance of infection.

A mass of information is contained in this report with detailed descriptions of the epidemiological findings and conditions of life and recommendations as to the control of the disease which in their instance upon modifications of existing customs rather than radical alterations which would probably antagonize the people display the wisdom and experience of the author. The untimely death of Dr Bardwell is a severe loss to the cause of tuberculosis but in this report he has left a model upon which future investigations may well be based.

VOGEL (E) & RIQU (M) *Les maladies épidémiques endémiques et sociales dans les colonies françaises pendant l'année 1937* *Maladies sociales Tuberculose* [Epidemic, Endemic and Social Diseases in the French Colonies during 1937 Tuberculosis].—*Ann de Méd et de Pharm Colon* 1939 Apr Vol 37 Supplement. pp 487-506 [Summary appears also in *Bulletin of Hygiene*]

In French West Africa 5 142 cases of tuberculosis were discovered in 1937 compared with only 1 833 in 1936 but the disparity is probably due to the improved services in the dispensaries since the proportion of tuberculosis in the total diseases found has hardly changed. Of the whole 87.6 per cent were cases of pulmonary tuberculosis. Fibro-caceous disease with frequent extensions is common and the patients are often not seen until the stage is advanced. Treatment is difficult but BCG vaccination is regularly carried out by the maternity staffs. In Dakar 1,563 vaccinations were thus performed. The disease is a serious menace in Dakar and the only certain prophylaxis is isolation in hospital but since the natives will not accept hospital treatment until a late stage this is obviously inadequate.

In Equatorial Africa there were 825 cases compared with 1 097 in 1936. In Madagascar there is a special dispensary. Collapse therapy has been given to 59 native patients. In Indo-China the numbers showed an increase to 48,120 and the disease is a great social danger. In Cochun-China there were 14,508 cases and pneumothorax was induced in 213. Other methods of collapse were also tried, and a hospital-sanatorium opened in 1933 has now admitted 388 patients of whom 133 have died. A preventorium for children has been commenced and 27,903 BCG vaccinations given. In Tonking 23 179 cases were found. At Hanoi there is a special dispensary and 13 410 BCG vaccinations were given. In the Pacific and Atlantic groups the numbers are much smaller as are the populations concerned.

Tuberculin testing of representative groups of natives was carried out in a number of places. Some of these results have already been abstracted in the *Bulletin of Hygiene*.

It is evident that the French are taking steps to control what is obviously a serious disease in the empire. It is advised that Europeans suffering from tuberculosis should be repatriated from West Africa for treatment.

WILLIAMS (George D) & APPLEWHITE (Joseph D) Tuberculosis in the Negroes of Georgia. Economic, Racial and Constitutional Aspects.—*Amer Jl Hyg* 1939 Mar Vol. 29 No 2 Sect. A. pp 61-110 With 4 figs [37 refs] (Summary appears also in *Bulletin of Hygiene*)

This is a detailed and careful study of 705 coloured non tuberculous persons and 138 coloured tuberculous subjects in Georgia, U.S.A. to assess the influence of habitus race and other factors on the incidence of tuberculosis. It should be read by all interested in the tuberculosis of native races.

The results of an anthropological study which was very fully carried out are treated statistically and the conclusion is arrived at that the Georgia series is a representative racially mixed Negro sample and that the conclusions drawn from a study of it are based on unbiased, unselected, adequately determined data. There is no doubt that tuberculosis takes a disproportionate toll among the negroes and it has been held that susceptibility is a racial characteristic and by CARTER that the darker negroes show less resistance than the lighter. The present investigation however failed to reveal any difference in incidence or (probably) in resistance in the miscegenetic types studied.

Since the time of Hippocrates it has been seen that tuberculosis is frequently associated with a certain physical habitus. In the present study in which negroes are compared not with whites but with negro-whites extensive measurement data (which do not and should not include the changeable feature of body weight) show that the various negro types are indistinguishable in bodily proportions and that the differences between the tuberculous and the non tuberculous can be explained as effects of the disease and not therefore, as predisposing factors.

A survey of the socio-economic conditions of the negroes studied brings out the fact that one group consisting of negroes with a greater degree of white admixture has an environmental advantage over other coloured people of the community. The reason for this may well be their interest in emulating the white side of their ancestry. At the same time the incidence of tuberculosis in this group is less frequent than in the others. In general it was found that gross overcrowding occurred among the mass of the negroes investigated and that this was related to the economic status. Further it was shown that tuberculosis was largely a matter of house contact and that overcrowding and contact possibilities were least in the more advantageously situated group referred to above. In this respect therefore but not directly racial mixture plays a part in the epidemiology of the disease.

In discussing prevention and control the authors emphasize the importance of preventing the mass infection which too commonly takes place in such communities and refer to the finding of OPTIE that diseased negroes like other communities whose experience of tuberculosis is of comparatively recent date tend to scatter tubercle bacilli in vastly greater number for much shorter periods of time than those affected with the usual chronic type of pulmonary tuberculosis. The incidence of mass infection can be greatly diminished by provision against overcrowding. Free institutional care is often given only to those who show some possibility of improvement while those with advanced disease are left to spread their infection at home. This

policy attempts to prevent mortality of the individual while permitting morbidity and mortality of the group.

The programme suggested for a campaign to control tuberculosis in the American negroes does not accept the view that in resistance they differ greatly from the whites and recent experience of collapse therapy supports this conclusion see also *Bull of Hyg.* Vol. 14 p. 128]. It is based on the principle of prevention of mass infection and may be summed up as to "identify the infected, isolate them and better the living conditions of this population generally" [Presumably by the infected are meant those actually diseased. Readers will see the similarity between these basic principles and those advocated in England by Lissant Cox — "Find, isolate, educate and treat the adult positive case."] C W

REVIEWS AND NOTICES.

FIELD (J W) *Notes on the Chemotherapy of Malaria.*—*Bull Inst. Med Res. Federated Malay States.* 1938 No. 2 pp vii+180 With 39 figs.

This short, up-to-date publication by an author with large experience, will be welcomed by malarialogists. It is based on a series of lectures delivered in Singapore, at the 4th International Congress on Malariology. The literature on the subject has been widely consulted and quoted with the author's own views. The reader feels that many lacunae in his previous knowledge have been filled up.

There is a brief historical introduction dealing with quinine, the advent of new synthetic drugs and the development of new methods in the treatment of malaria, associated with the use of induced malaria in the treatment of G.P.I. patients. It has now become necessary as the author points out to desire an antemalarial drug in parasite

has also its limitations in drug testing as the author states and actually the above-mentioned amudine was ineffective against *P. relictum* infections of canaries, although moderately active in B T and monkey malaria.

The history and use of atebryn is also discussed fully. Evidence is adduced that a combination of atebryn and plasmoquine is not desirable but favourable reports on atebryn tablets have been received from India and elsewhere. Other drugs which have failed to stand the test of experience are briefly described.

Specially valuable are the suggestions outlined for the treatment of malaria in various circumstances. Quinine plasmoquine and atebryn have all been used successfully in pregnancy complicated by this disease. In some communities B W F has disappeared as the result it is claimed, of taking small daily prophylactic doses of quinine.

The question of chemoprophylaxis is dealt with from a theoretical and practical standpoint and indications for its employment outlined. It is still doubtful whether any antimalarial, given in non toxic doses can prevent infection following the bite of an infected mosquito. Post prophylactic recrudescence of attacks is a problem of considerable gravity. The author has serious doubts about the value of attempting to eradicate malaria by drug treatment alone.

The bulk of evidence regarding the influence of chemoprophylaxis on natural immunity suggests that the latter process is slowed down during treatment but that pre-existing immunity is probably not lost. It is concluded that the interests of scattered populations are probably best served by mutual adjustment between parasite and host so long as life is safeguarded by a judicious use of quinine.

Apart from some minor mistakes in print such as representing neo-salvarsan with two sodium atoms the compound C77 with a double-bond in the bridge structure of the piperidine ring and the Cl atom by two capital letters the book is well produced. Schülemann's name is consistently spelt with a single 'n'.

The appendix contains the 4th General Report of the Malaria Commission of the Health Organisation of the League of Nations and is most valuable. The reviewer is glad to have had the opportunity of reading this book.

J D Fulton.

BISQUERRA (E D) *Le traitement du kals-azar* [Treatment of Kala Azar]—273 pp With 13 graphs. [Bibliography] Algiers Imp Navarro.

This book is a thesis presented to the Faculty of Medicine in Algiers and as such is a review of the literature on the subject of its title rather than an account of personal experiences in the treatment of the disease. In fact there is little evidence that the author has had any personal contact with cases or has treated any on his own account. Nevertheless, the literature of the subject running to over three-hundred and fifty references, has been carefully reviewed and various conclusions have been drawn. The chief of these appear to be that once diagnosed, the disease must be treated by a short and intensive course of some antimony derivative and that after the course the case must be watched for a month before deciding that further treatment is not necessary. The clinical course alone will decide this point. For a further period of five months the patient must be under observation,

so that the first indications of any relapse can be detected. If after this there is continued good health it is safe to conclude that a cure has resulted.

C. M. Wenyon

SIMMONS (James Stevens) [B.S. M.D. Ph.D. S.D. etc.] with the Collaboration of George R. CALLENDER M.D. Dalferes P. CURRY M.D. Seymour C. SCHWARTZ B.S. M.D. Dr. P. H. & Raymond RANDALL, D.V.M. *Malaria in Panama.—Amer. J. Hyg. Monographic Series* 1939 Jan. No. 13 pp. xv+328 With 32 figs (2 folding) [Bibliography] 1939 Baltimore Johns Hopkins Press. [\$1.00]

For a book in which the subject matter is contained in just over 300 pages this volume is extraordinarily comprehensive yet throughout the work one is impressed with the conviction that the authors one and all are thorough masters of the material with which they are dealing.

The climatology and physical geography of the Panama Canal region in their special relationship to the presence of malaria are adequately discussed and sufficient historical data are given to afford a useful background to the general account of the attempts to construct a canal previous to the final successful effort of the United States Government.

The account given of present conditions in the Panama Canal area is a useful corrective to the widely prevalent idea of the unconstructed that malaria has been completely wiped out from Panama. In this connection a clear description is given of the distinction to be drawn between the areas sanitated by the public health services, civil and military, of the United States authorities and the unsanitated areas lying beyond the Canal Zone which are a constant menace to the former on account of the severity and extent of malaria prevalence in these uncontrolled surrounding areas.

It is shown that the control of the disease is more effective among the employees of the Canal Zone than among the United States troops stationed in the area—a condition probably caused by the greater exposure of the latter to infection in the performance of their duties in areas or among populations imperfectly protected.

It is pointed out that in spite of the enormous improvements effected by anti-malaria operations malaria is still the commonest single disease among Canal employees. Thus between the years 1914-1938 the malaria admission rate has averaged between 11 and 19 per 1,000 admissions and this figure is being maintained.

A mass of details impossible to enumerate here is given in tables which should be of great help to students of malariology and the same remark applies to the enumeration of the various species of *Anopheles* their distribution and habitats.

An account of the various methods of malaria control employed in the Canal Zone need not be specifically mentioned here as they are on orthodox lines and now well known, but certain points emerge from the description which are worthy of note. These are —

(a) The Health Department of the Panama Canal has been able to sanitize effectively only relatively small areas near the principal towns while no practical and economical method has been devised for dealing with the country in general. The same remarks apply to military posts.

(b) The introduction of agriculture and hence settlers into the Canal Zone and the development of road transport have led to an increase of malaria owing to the less strict control exercised over the settlers who are largely negroes.

(c) The failure of drug treatment by itself to control malaria.

(d) Permanent stability in control of malaria has not and probably never will be achieved in the Canal Zone. Any relaxation of vigilance or failure to apply proved methods of prevention will be rapidly followed by a deterioration in sanitary conditions generally and especially as regards malaria prevalence.

The book is too full of detail to be read as a narrative but the authors are to be congratulated on producing a work which will obviously become a source of reference for students of public health in the tropics and especially for those interested in the history of what is probably the greatest engineering feat performed in the tropics under conditions where sanitary science was a deciding factor in success. That the style in which the book is written is particularly facile and explicit to a degree which many books of science fall far short of adds appreciably to its value.

H E Shortt

SOCIEDAD ARGENTINA PATOLOGÍA REGIONAL. Novena Reunión celebrada en Mendoza 1, 2, 3 y 4 de octubre de 1935. En homenaje a la memoria de Carlos Chagas. Tomo Tercero [Report of Ninth Congress of Northern Argentine Pathological Society, Vol 3]—pp 1417–1993. With numerous illustrations. 1939. Buenos Aires. Imprenta de la Universidad.

The first volume of papers read at the Ninth Congress of the Society in October 1935 was issued in 1936 and was reviewed in this *Bulletin* [1936 Vol. 33 p 971] the second appeared in the following year but was not sent to the Bureau. The third has only recently been published. This delay of nearly four years is greatly to be deplored as the subjects dealt with were of no little interest at the time but have lost much of their importance now and no longer call for detailed abstract. This volume contains altogether 50 articles 35 of them by Professor MAZZA and his colleagues. The following are still worth bringing to the notice of readers. ARAGÃO has contributed some notes on the Ixodidae of the Argentine and ORFILA writes of the Simuliidae and their distribution both of these are useful for reference. REGENDANZ & MUÑOZ have investigated the transmission of typhus in San Pablo by *Rhipicephalus sanguineus* and show that the larval nymph and adult stages are infective but that infection is not transmitted to the next generation the ova not being infected. There are two papers on Chromoblastomycosis the condition being due in each case to *Hormodendron chaquense* which is described and depicted. Fifteen papers are contributed on some aspect or other of Brucellosis, epidemiological, epizootological, clinical or serological. Its presence is almost natural in a cattle country and the findings detailed in the various articles are now well known. Several cases of American cutaneous leishmaniasis are presented with illustration of the lesions. MAZZA and CORNEJO discuss the question whether cutaneous leishmaniasis invades the bone beneath and describe a case in which lesion over the metacarpals was associated with localized thickening of the

periosteum of these bones and the first phalanges. The latter change was not extensive and was probably irritative merely from the overlying inflammatory condition. H H S

TROWELL (H C) [M.D. M.R.C.P. (Lond.) etc.] *Diagnosis and Treatment of Diseases in the Tropics*. Baillière's Medical Manuals for Africans—pp xvi+205 With 35 figs. 1939 London: Baillière Tindall & Cox, 7 & 8 Henrietta Street Covent Garden, W.C.2 2s 6d]

It is recognized by thoughtful teachers of medicine that the principal difficulty in the preparation of text-books for African Natives lies in the nice discrimination between over-simplicity and over-complexity in both the matter and the manner of its presentation. The author is well aware of this difficulty and, drawing from his considerable experience in the teaching of nursing orderlies and of students of the Mulago Medical School, has set out in clear but not childish language (which is too often used in such work) what he considers to be the bare minimum necessary for any comprehension of medical and surgical diseases. It is made clear that the book is not intended to be read without tuition, and the aim of the instruction given is that the orderly should be able to nurse intelligently. It is indeed an encouraging sign that with increasing specialization of teaching there should be an increasing demand from the native of more than mere routine obedience to orders.

The book opens with a chapter on the general principles of medical diseases, followed by one on common signs. Then follow chapters on the general principles of surgical diseases, common surgical diseases, special varieties of inflammation, and special surgical diseases. Part 3 deals with general fevers, fever due to local inflammation, diseases of the digestive tract and special medical diseases. Part 4 is devoted to special diseases, including venereal disease, yaws and others not included in earlier chapters. At the end of each chapter is a summary and a group of questions such as might be set in an examination. Illustrations are plentiful and much use of heavy type has been made.

The arrangement of the various diseases in the chapters is not in accordance with usual practice, but this is a small matter. The point is that if an orderly knows this book well, and grasps the reasoning which is presented he will be able to nurse intelligently. In the opinion of the reviewer the book is not beyond the capacity of the ordinary African orderly. C H

TROPICAL DISEASES BULLETIN.

Vol. 36.]

1939

[No 11]

SUMMARY OF RECENT ABSTRACTS

IX. LEPROSY *

Classification —RABELLO (p 290) suggests a method for the details of which the original abstract should be consulted and WADE (p 290) has also contributed to this subject RYRIE (p 550) uses a method in which letters are employed to signify the resistance of the patient and KUSVETZOW (p 550) advises that four phases of the disease should be recognized

Epidemiology —There are a few lepers still in Great Britain but MACLEOD (p 545) shows that the majority are adults who have returned from tropical countries. In Italy the same process is occurring in peasants who return after emigrating to Latin America. BROCCIERI (p 285) quotes the case of a woman who had never been away from Italy and gave no history of contact but who acquired leprosy probably he considers through contact with a returned leprous emigrant

In Estonia PARMAKSON (p 883) shows that cutaneous disease is more common than neural Women are more frequently attacked than men and the highest incidence is in the age groups 30-39 The average duration to death was 15 years and 19.3 per cent. of patients recovered under treatment of whom 11.4 per cent later relapsed.

DALGAMOUNI (p 558) estimates that there are 15 000 lepers in Egypt. He describes the work done in the clinics.

In S.E Nigeria OBERDÖRFFER (p 882) found from 3 to 5 per cent of the population to be infected but there were comparatively few women and children affected (but see below DAVEY) The disease was most active in the dry months and he associates high rates with the consumption of coco-yams which contain toxic substances. DAVEY (p 882) reports that it is the native custom to segregate lepers in small villages close to the main villages but in one main village there still remained 65 lepers. In the areas examined, female cases outnumbered male by almost 2 to 1 Slightly higher female than

* The information from which this series of summaries has been compiled is given in the abstracts made by the Sectional Editors in the *Tropical Diseases Bulletin* 1938 Vol 35. References to the abstracts are given under the names of the authors quoted and the pages on which the abstracts are printed.

male rates were found in the lower Congo by the FORLAMI staff (p. 284) and the total rate varied from 1.7 to 4.3 per 1,000. In Basutoland, GERMOYD (p. 286) reports a rate of 3.2 per 1,000 of which 90.5 per cent were mild neural cases. STRACHAN (p. 285) shows, in the same country that the average age on admission to hospital was 36.5 years and all except a quarter had had the disease for less than 2 years on admission.

CILENTO (p. 287) reports that leprosy is a serious problem in New Guinea and that increasing numbers are being found in the Solomon Islands. AUSTIN (p. 545) from Makogai shows that it is more severe in Fijians than in Indians.

Contact—The subject of contact is touched upon by several authors. MOISER (p. 881) considers that leprosy is spread in S. Rhodesia during native beer drinks and advises that lepers should, therefore, be prohibited from taking part. In French Equatorial Africa LE BIHAN (p. 545) found a very high proportion (1,182 of 1,832 cases) of direct family antecedents. He considers that goitre which is very prevalent, does not predispose to the disease but that elephantiasis does. In Bengal LOWE (p. 883) found contact history in 80 per cent. of cases. The incidence was 4.38 per cent. and infections were found mainly in early life and mainly in males, in whom the disease was severe. The majority of patients showed neural infections. Infection was traced to open cases in half of the patients reported by COCHRANE and RAJAGOPALAN (p. 885) who found a rate of 6 per cent. in a school survey in Madras.

INNES (p. 832) considers the distribution in the British Solomon Islands to be that of a small group or family disease, and found an incidence rate of 1.02 per cent. [see CILENTO above]. At the Nauru Island segregation camp CLOUSTON (p. 291) shows that 5 of 24 children born to lepers but separated at once from their parents, developed the disease after the age of three. It was not however possible to be certain that no contact had taken place with other lepers on the island.

On the other hand, in the Dutch East Indies LAMPE (p. 884) found that infections other than familial account for 66 to 80 per cent. of cases and only rarely were as many as three cases found in one family.

McCoy (p. 557) stresses the importance of family transmission, but admits that the exact mode is uncertain. He does not (p. 545) think that climatic conditions can explain the varying trends of leprosy in the United States, nor does he see convincing evidence that any control measure yet attempted has been successful in retarding spread, though he approves of attempts by the colony method. ARCOCK and MCKINLEY (p. 884) think that inherited susceptibility is a factor in contact spread.

In an examination of 15,424 contacts in Mexico URUERA (p. 546) reports that 83 patients, who would ordinarily have escaped observation, were found. Housing conditions were bad and 6,739 persons, including 2,717 children were living in the same rooms as lepers. Serious nodular cases accounted for 30.1 per cent. of the 3,882 lepers studied. In the Argentine BALISA and BASOMBRIO (p. 881) show that the incidence on the coast is higher than in the dry Andes area, which supports the theory of ROGERS of the influence of humidity. High density of population also favours high incidence but conjugal infection was rare in the series examined and only occurred in bacillary positive cutaneous cases. In three-quarters of 892 cases the first symptoms were cutaneous. DO PATIO and PEREIRA (p. 286) advise

weekly examinations of contacts so that treatment can be commenced at an early stage. The majority of contacts who develop disease do so within 3 years but the interval may be 5 years or more. PORTUGAL (p 284) records the following contact figures family 11 per cent, conjugal 9.2 per cent other 16.7 per cent. The heaviest incidence in the 873 cases studied occurred between the ages of 20 and 40 and in general males were rather more frequently attacked than females. Cutaneous and mixed forms accounted for from half to two-thirds in different areas.

Bacteriology—ADLER (p 293) succeeded in infecting the Syrian hamster *Cricetus auratus* with material from human leprosy nodules having previously removed the spleens of the animals. Evidence of multiplication of bacilli was obtained in 3 of the 4 animals used and of generalization in one of the three. With ASHBEL (p 888) he showed that leprosy bacilli in thin sections of tissue dried over sulphuric acid were still able to infect hamsters after 7 days. WATANABE (p 888) has succeeded in subtransplanting for three generations granulating tissues resulting from inoculation of human leprosy material into rats previously treated with venom.

Cultivation—MCKINLEY and DE LEON (p 292) have subcultured the bacilli isolated in 1931 through 60 generations during which no luxuriant growths have developed. This is in contrast with the experience with other acid fast bacilli thought to be *Mycobacterium leprae*. They describe a gas tension incubator for mass culture in controlled atmospheres used in conjunction with hormone glycerol agar medium. SALLE and MOSER (p 292) used this gas environment which is based on an oxygen-carbon dioxide mixture, and succeeded in cultivating *Mycobacterium leprae* on glycerine veal agar slopes. They were also successful in cultivation on glycerine veal agar with the addition of embryonic chick tissue. Positive results with acid fast and non-acid fast rods were obtained in 190 of 311 tubes and flasks when the inoculum consisted of nodules removed aseptically and minced.

FAURE BEAULIEU and BRUN (p 887) claim to have cultivated the organism and to have found mutation between the acid fast and non-acid fast granules which they have observed in leprosy lesions. PAPAIOANNOU (p 892) reports successful cultivation and transmission of human and rat leprosy bacilli to various rodents.

MANALANG (p 887) also reports acid fast and non acid fast forms of *Mycobacterium leprae* in both treated and untreated lesions the latter being regarded as young or degenerating forms. In glands kept *in vitro* with preparations of *H. wrightiana* especially when these are applied intermittently the acid fast forms largely change to the non-acid fast. This may explain the greater efficiency of intradermal injections of these preparations when they are applied intermittently.

ANDERSON *et al* (p 294) report on the chemical constitution of acetone-soluble fat of *Mycobacterium leprae*.

Since ordinary methods of disinfection fail to remove leprosy bacilli living or dead from instruments BEAUDIMENT and TIVOLLIER (p 888) recommend 1 to 2 per cent of soda for this purpose.

RADNA (p 551) reports positive bacteriological results in the examination of the sediment of dehaemoglobinized venous blood in 84.31 per cent of cutaneous and mixed cases. LLERAS ACOSTA (p 551) has isolated an acid fast bacillus in culture experiments on the blood of patients with nodular disease. He used Petragram's medium and succeeded in 20 of 66 patients. With this bacillus as antigen

he found positive complement fixation tests to be given by 99.38 per cent. of bacteriologically confirmed lepers, 92.5 per cent. of clinically diagnosed lepers, 11.38 per cent. of children of lepers, 18.48 per cent. of healthy contacts and 38.12 per cent. of cured patients. Only 0.09 per cent. of normal persons were positive. Intradermal tests performed with a leprolin prepared from the bacillus were positive in normal controls and negative in lepers which he explains as an indication of immunity. [See also SATO below.] SAENZ (p. 887) repeated these serological tests, but used as antigen an acid fast bacillus obtained from tap water. His results were identical with those obtained by LLERAS ACOSTA. He found also that the two bacilli produced on intradermal injection the same reactions as were given by other acid fast saprophytes. SATO (p. 559) recovered 14 strains of saprophytic acid-fast bacilli from 30 rats infected with rat leprosy. Serological tests with a variety of antigens, including preparations of leprosy and tubercle tissues, produced positive results in from 0 to 25 per cent. of infected rats and in from 5 to 100 per cent. of human leprosy infections. Normal rats and healthy persons were all negative. By precipitin tests, HENDERSON (p. 292) found group affinity in 13 of 15 strains of acid fast bacilli isolated from lepers, and shows that these strains have a group relationship with *Mycobacterium*. [The findings of the three latter workers do not invalidate the claim that the bacillus of Lleras Acosta is useful in the serological diagnosis of leprosy but they constitute a strong argument against its specificity. The finding of acid-fast bacilli in blood, which in such work is usually treated with various reagents has in recent years been a highly controversial subject.]

RAHELLO and PLATO (p. 889) found the Witebaky-Klingenstein and Kuhn complement fixation test (with a tuberculin antigen) to be positive in 68 per cent. of tropho-neurotic cases, 60 per cent. of macular cases and negative in 70 per cent. of cutaneous. This is the opposite of the results of the Mitsuda test.

Positive Wassermann and Kahn tests in mild and early cases are considered by MUIR and ROY (p. 532) to indicate coincident spirochaetal disease but not necessarily so in advanced cases, especially if subject to leprosy fever. GUNDERSEX and BERNER (p. 552) regard them as indicating syphilis.

Skin tests.—In the *Monthly Bulletin of the Bureau of Health* Manila (p. 295) is a statement of the results of 5,174 skin tests performed with products derived from different types of acid-fast organisms including those isolated from cases of leprosy and the strains cultivated by McKINLEY and SOULE [see McKINLEY and DE LEON above]. In no instance did the positive reactions in leprosy exceed the negative and no definite conclusions can therefore be drawn.

The leprolin test was used by CAMPOS (p. 553) on 331 healthy children of lepers. He found that positive results increased with age from 22.6 per cent. under 3 years to 88 per cent. over 13. Children removed from parents at birth were negative. The test is negative in the uninfected and the heavily diseased, and positive in healthy contacts and in those with slight lesions. RADNA (p. 889) similarly reports negative reactions to the Mitsuda test in active cutaneous, and positive in nerve and recovering cases. A positive result in a previously negative case is a good sign. RODRIGUEZ (p. 553) regards negative results in cutaneous cases as due to anergy and positive

reactions in such cases as constituting a favourable sign. PARMARSON's results (p 554) support this latter conclusion.

Clinical—Sternal puncture was used in diagnosis by LOWE and DHARMENDRA (p 291) who found acid fast bacilli in 16 of 32 patients with nodular disease but in only 1 of 18 nerve cases. Gland puncture yields the bacilli in nodular disease but VAN BREUSEGHEM (p 291) finds it of no value in nerve leprosy. He uses a sweating test by covering the area of skin with Tr iodine allowing to dry covering with starch and then attempting to provoke sweating by light exercise. If sweating occurs the starch is turned blue.

DUBOIS *et al* (p. 290) point out that histological diagnosis in early leprosy is not always certain and confusion with tertiary syphilis may occur.

Tuberculoid leprosy—RABELLO (p 548) argues that tuberculoid leprosy presents clinical and pathological changes similar to those seen in the Besnier Boeck sarcoid and Schaumann's syndrome, but REENSTIERNA, admitting the similarity of the skin lesions and of the radiological appearances in bones and lungs states that the leprosy bacillus has not been shown to be capable of producing the systemic reactions of Schaumann's syndrome. FERNANDEZ (p 289) regards the tuberculoid leprosy reaction as an allergic phenomenon with intense tissue reaction in the early stages and later necrosis due to invasion of the sensitized tissues by the bacilli, which increase in number as the reaction diminishes. DA ROSA (p 550) holds that the lepra reaction is allergic but that it is not specific since the bacilli are not found in the skin.

HUGHES (p 547) regards the tuberculoid form as a stage in the natural evolution of immunity so that it is common in races which have for long been associated with leprosy.

TISSETIL (p 289) describes 4 cases in which tuberculoid lesions thought to be primary leprosyous chancres were present in children. In 42 neural cases in Madras 7 were classed as major tuberculoid, 6 as minor tuberculoid or intermediate 5 as retrogressive papulate and 24 as simple by WADE *et al* (p. 547). WADE and FRASER (p 289) report that tuberculoid lesions are fairly common in S China being found clinically in 23 of 225 patients examined. In all except 1 of 31 neural cases from which biopsy material of the leprides was taken tuberculoid changes were seen.

WADE *et al* (p 885) describe the microscopical changes in nerve lesions. Activation may be related to climatic conditions. Changes in the finger prints of 12 per cent. of neural cases 9 per cent. of macular and mixed and 6 per cent. of nodular cases are reported by VIEIRA and DE ABREU (p 547). The changes are first evident in the little and ring fingers which points to ulnar distribution.

MITSUDA and NAGAI (p 288) attribute the alopecia frequently seen in leprosy over the course of the larger veins to infiltration of the perivascular lymph spaces and consequent pressure around the hair papillae causing malnutrition and atrophy.

OBERDÖRFFER (p 284) found nasal lesions in 62 per cent. of patients in the Idu leper colony in S Nigeria. These were mostly localized, especially on the anterior nasal septum.

The basal metabolism in leprosy according to JUNIOR (p 283) is increased, but in quiescent cases tends to fall to normal. The leprotic reaction increases the rate.

RYNIE (p. 886) from an experience of 600 cases shows that leprosy does not influence pregnancy but pregnancy causes slow progressive spread of the disease in the later months, probably through mineral depletion, since the exhibition of calcium tends to check this aggravation. The placenta and cord are not affected and children removed at birth remain healthy.

NAKAJYO and SUZUKI (p. 294) obtained cultures of tubercle bacilli from the sputum of 30 lepers in 100 examined.

Control and treatment.—In the Sudan it is held that although leprosy is well under control, improved diet and standards of living will be necessary for its permanent eradication (p. 286). CILENTO (p. 287) advises re-examination of contacts for every 6 months for 5 years in Australian territories. For the aboriginals only segregation is likely to be effective since they fear medical treatment. The development of agricultural and industrial work by inmates of leper colonies is shown by reports from N Nigeria (p. 284) Basutoland (p. 285) and Egypt (p. 286). But in connexion with segregation MUIR (p. 546) considers that compulsion should only be applied by the community itself—never from without. Treatment by general methods, combined with chaulmoogra, is important.

Chaulmoogra.—A comprehensive account of this and allied oils has been written by SCHLOSSBERGER (p. 296) and LOWE and DE (p. 556) give tests for the suitability of hydnocarpus oil for injection. Decomposition of the esters of *H. zeyheriana* oil is responsible for irritation occasioned on injection. This can be removed, according to COLE and CARDOSO (p. 296) by neutralization and blowing out with steam. LABERNADIE and GUICHARD (p. 800) report that the neutralization of hydnocarpus oil by the procedure of Le Naour and Roubaud yields a product free from glycerine but in which the content of active glycerides is slightly increased [not as stated in the original abstract "containing little active glyceride"]. BARÉ (p. 891) reports success with intravenous neutralized chaulmoogra oil.

WOODMAN (p. 285) speaks favourably of chaulmoogra treatment in early leprosy in the Sudan, and of the value of settlements in segregation and MOISER (p. 681) reports that 80 per cent. of patients obtained benefit from moogrol treatment in a hospital in S Rhodesia. At the Urnakoh Leper Colony in N Nigeria a mixture of hydnocarpus oil 25 per cent. its esters 25 to 62½ per cent. with 12½ per cent. of cod liver oil, 12½ per cent. olive oil and 4 per cent. creosote in doses of 1 to 10 cc. is used for treatment by injection (p. 284).

Intradermal treatment is reported by STRACHAN (p. 286) to be popular in Basutoland. LIMA (p. 554) speaks highly of the intradermal infiltration of chaulmoogra and its derivatives: the majority of patients are improved but chaulmoogra does not seem to have any effect on ocular lesions. VALLE (p. 549) in fact states that these preparations are liable to provoke dangerous reactions in lesions of the eye and therefore advises that they should not be used in such complications. The anterior segment of the eye may be invaded from the lids and cauterization, peritomy and iridectomy may be necessary to prevent invasion. He endorses the value of trypan blue treatment.

In tuberculous lesions RYRIZ (p. 553) finds intradermal chaulmoogra esters of little use though this method is the best in cutaneous disease with abundant bacilli. Subcutaneous hydnocarpus oil gave the best results in a series of tuberculous cases. He (p. 885) describes the acute sloughing tuberculous disease which is only seen in Malaya and

which is intractable except by large local injections of hydnocarpus oil and unguents of hydnocarpus ointment. On the other hand TISSEUIL (p 556) obtained disappearance of tuberculoid lesions by intradermal injections of chaulmoogra oil. Olive oil was inert.

In ulceration of the foot LOWE and CHATTERJI (p 297) advocate the injection of hydnocarpus preparations along the course of the tibial nerve since infiltration of that nerve is present in such cases. Surgical decapsulation of the nerve relieves pain but does not induce healing. BOUSEFIELD (p 549) after removal of necrosed bone uses mild antiseptic solutions of 0.5 to 2 per cent. copper sulphate together with intramuscular and local intradermal injections of iodized chaulmoogra esters. This treatment combined with plentiful good food is very successful.

PAGET (p 297) investigated the components of the oil of *Carpotroche brasiliensis* which is used for treatment of leprosy in Brazil, and which contains the characteristic chaulmoogric and hydnocarpic acids. TISSEUIL *et al* (p 890) report that ground nut oil has only a feeble action in leprosy but that Gorli butter produces slow improvement in tuberculoid cases. TISSEUIL (p 298) reports favourable results with synthol soufflé in the treatment of perforating ulcers.

Methylene blue—LE BIHAN (p 545) advocates this drug for pains when combined with chaulmoogra treatment. Remarkable and promising results are reported by DE ALMEIDA and DE MOURA COSTA (p 889) from the administration of 2 or 3 intravenous injections of 5 to 10 cc. methylene blue (strength not stated) followed when the drug is no longer being excreted in the urine by placing the patient in a pressure of 2.5 to 3.5 atmospheres of oxygen for varying periods. Clinical improvement occurs with great alteration and diminution of the bacilli in the lesions. The treatment is based on the fact that anaerobic organisms cease to develop under an oxygen pressure of 4 to 5 mm. mercury. ROGERS suggests a trial of this method with chaulmoogra in place of the methylene blue.

To overcome the reactions which occur to intravenous methylene blue TISSEUIL (p 891) uses intravenous injections of 0.1 per cent. of that drug in 4 per cent. glucose and 0.4 to 0.9 per cent. saline. If fever persists the injections should be stopped for a time.

Other drugs—TISSEUIL (p 300) reports 4 patients with laryngeal leprosy relieved rapidly by yohimbine by the month. FLORIANI and FLORIANI (p 298) used a 2.5 per cent. aqueous solution of the total alkaloids of the bark of *Aspidosperma polyneuron* in the Argentine for intramuscular injection in leprotic ulceration. Good results were obtained in 15 cases. Others were given preparations of *Bixa orellana* and both drugs are advocated.

Tellurium and its sodium salt retard the development of rat leprosy diminishing the vitality of but not killing the bacilli. MARCHOUX and CHORINE (p 297) used the method in man but the results though beneficial, were not lasting. Carbon dioxide snow proved useful in a case of leprosy with extensive rose coloured annular plaques treated by VIGNE *et al* (p 299).

Vaccines and Sera—PEREIRA (p 299) reports apparent benefit from the use of Vaudremer's vaccine in those with fever and debility and in early nerve lesions. In ocular cases it may be dangerous and it has no effect on nodules, ulcers or sensory disturbances. Temporary improvement due to antirabic vaccine is attributed by TISSEUIL and GUILHAUMOU (p 299) to simple biotherapy. REENSTIERNA (p 299)

RYKIE (p. 886) from an experience of 600 cases shows that leprosy does not influence pregnancy but pregnancy causes slow progressive spread of the disease in the later months, probably through mineral depletion, since the exhibition of calcium tends to check this aggravation. The placenta and cord are not affected and children removed at birth remain healthy.

NAKAYO and SUZUKI (p. 294) obtained cultures of tubercle bacilli from the sputum of 30 lepers in 100 examined.

Control and treatment—In the Sudan it is held that although leprosy is well under control, improved diet and standards of living will be necessary for its permanent eradication (p. 296). CILENTO (p. 287) advises re-examination of contacts for every 6 months for 5 years in Australian territories. For the aboriginals only segregation is likely to be effective since they fear medical treatment. The development of agricultural and industrial work by inmates of leper colonies is shown by reports from N. Nigeria (p. 284) Basutoland (p. 285) and Egypt (p. 286). But in connexion with segregation MUIR (p. 546) considers that compulsion should only be applied by the community itself—never from without. Treatment by general methods, combined with chaulmoogra is important.

Chaulmoogra—A comprehensive account of this and allied oils has been written by SCHLOSSBERGER (p. 296) and LOWE and DE (p. 556) gave tests for the suitability of hydnocarpus oil for injection. Decomposition of the esters of *H. wightiana* oil is responsible for irritation occasioned on injection. This can be removed, according to COLE and CARDOSO (p. 296) by neutralization and blowing out with steam. LAKERKADIE and GUTHARD (p. 800) report that the neutralization of hydnocarpus oil by the procedure of Le Naour and Roubaud yields a product free from glycerine but in which the content of active glycerides is slightly increased [not as stated in the original abstract, 'containing little active glyceride']. BAKI (p. 691) reports success with intravenous neutralized chaulmoogra oil.

WOODMAN (p. 285) speaks favourably of chaulmoogra treatment in early leprosy in the Sudan, and of the value of settlements in segregation, and MOISER (p. 681) reports that 80 per cent. of patients obtained benefit from moogrol treatment in a hospital in S. Rhodesia. At the Urukoh Leper Colony in N. Nigeria a mixture of hydnocarpus oil, 25 per cent. its esters 25 to 62½ per cent., with 12½ per cent. of cod liver oil, 12½ per cent. olive oil and 4 per cent. creosote in doses of 1 to 10 cc. is used for treatment by injection (p. 284).

Intradermal treatment is reported by STRACHAN (p. 286) to be popular in Basutoland. LIVA (p. 554) speaks highly of the intradermal infiltration of chaulmoogra and its derivatives. The majority of patients are improved but chaulmoogra does not seem to have any effect on ocular lesions. VALLE (p. 549) in fact, states that these preparations are liable to provoke dangerous reactions in lesions of the eye and therefore advises that they should not be used in such complications. The anterior segment of the eye may be invaded from the lids and cauterization, peritomy and indectomy may be necessary to prevent invasion. He endorses the value of trypan blue treatment.

In tuberculous lesions RYKIE (p. 555) finds intradermal chaulmoogra esters of little use though this method is the best in cutaneous disease with abundant bacilli. Subcutaneous hydnocarpus oil gave the best results in a series of tuberculous cases. He (p. 585) describes the acute sloughing tuberculous disease which is only seen in Malaya and

which is intractable except by large local injections of hydnocarpus oil andunctions of hydnocarpus ointment. On the other hand TISSEUIL (p 556) obtained disappearance of tuberculoid lesions by intradermal injections of chaulmoogra oil. Olive oil was inert.

In ulceration of the foot LOWE and CHATTERJI (p 297) advocate the injection of hydnocarpus preparations along the course of the tibial nerve since infiltration of that nerve is present in such cases. FAIRLEY (N Hamilton) *Methaemalbumin (Pseudo-Methaemoglobin)* [Correspondence.]—*Nature* 1938 Dec. 31 Vol. 142. No 3609 pp 1156-1157

— & BROMFIELD (R. J.) I. Pseudo-Methaemoglobin—Its Synthesis from Crystallalbumin and Alkaline Haematin. II. Pseudo-Methaemoglobin—Its Demonstration in the Marchiafava-Micheli Syndrome of Nocturnal Haemoglobinuria [Demonstration]—*Trans Roy Soc Trop Med & Hyg* 1939 Jan 28 Vol. 32. No. 4 pp 431-433

In a previous paper Fairley suggested the name pseudo-methaemoglobin for a new blood pigment formerly confused with methaemoglobin found in the plasma of blackwater fever cases. [This *Bulletin* 1937 Vol. 34 p. 841] This pigment is derived from extracorporeal oxyhaemoglobin. Fairley has since demonstrated the same pigment in nocturnal haemoglobinuria incompatible transfusion and pancreatic cyst fluid.

It has long been recognized that, on incubation solutions of haemoglobin yield methaemoglobin and later haematin. Fairley showed that when oxyhaemoglobin was incubated at 40°C for 24 to 72 hours in the presence of human plasma, pseudo-methaemoglobin was produced. Similarly when alkaline haematin was added to human plasma or serum, pseudo-methaemoglobin immediately appeared. This suggested that haematin was coupling with some protein to form a new compound. Apparently only human and simian plasma contained the constituent coupling with haematin to form pseudo-methaemoglobin.

Further work showed that alkaline haematin produced pseudo-methaemoglobin only with the albumin fractions and never with the pseudo-globulin or euglobulin fractions of serum protein. Of the albumin fractions only crystallalbumin proved capable of forming pseudo-methaemoglobin. Finally it was noted that whilst the intravenous injection of alkaline haematin into *Macacus rhesus* produced pseudo-methaemoglobin similar injections failed to produce it in rabbits.

Certain details are given concerning the spectrum of the synthesized pigment and its chemical and physical behaviour. From this work it is concluded that pseudo-methaemoglobin is modelled on the methaemoglobin pattern but that while the prosthetic group is similar the protein component is native serum albumin instead of native globin. The iron is held in the trivalent state and is even more resistant to reducing agents than methaemoglobin itself. In view of these findings Fairley proposes to change the name of pseudo-methaemoglobin to methaemalbumin.

It is noted that as methaemalbumin is never found within the corpuscles it cannot function as a respiratory pigment. It is derived from circulating extracorporeal haemoglobin liberated during intra vascular haemolysis or from blood which has escaped into

is present in certain localities only. The present note describes two cases of blackwater fever occurring in Egyptians who have not left the country.

This is followed by a discussion on the pathogenesis of blackwater fever in which the following remarkable sentence occurs. Apparently in Egypt urticaria in malaria takes the place of the much rarer condition blackwater fever. H Y

MARSHALL (F) Das Schwarzwasserfieber in Santo Domingo [Blackwater Fever in Santo Domingo]—*Arch f Schiffs u Trop Hyg* 1939 June. Vol. 43 No 6 pp 266-273 With 1 fig

In the islands of the Great Antilles which have a similar origin the distribution of tropical diseases is very different. In Porto Rico for example *Schistosoma mansoni* infections are widespread whilst in Santo Domingo the parasite is not found. Blackwater fever is common in Haiti and is not uncommon in Jamaica and Santo Domingo but it is extremely rare in Porto Rico. This is so much the more striking since the inhabitants of these islands belong to the same race and the climate soil fauna and flora are all similar.

Actually blackwater fever in Santo Domingo is not common about 40-50 cases yearly being recorded. The disease is chiefly found in the western portion of the Republic bordering on Haiti and particularly in the districts of Azua San Juan and Barahona. In these provinces malaria is also commonly met with.

Clinical details and the post-mortem findings of a case of blackwater are recorded at length. The author then passes to a discussion of four theories which have been advanced to explain the disease 1. that it is due to a specific organism such as a spirochaete 2. that it is due to a special malaria parasite which exhibits a particularly powerful haemolytic action 3. that it is the consequence of a sensitization to particular drugs (quinine) resulting from malaria and that it belongs to the allergic or anaphylactic reactions. After discussing these various hypotheses at some length the author concludes that the last is probably correct. H Y

FOY (Henry) & KONDI (Athena) Spleen Puncture Findings in Blackwater Fever—*Trans Roy Soc Trop Med & Hyg* 1938. Nov 26 Vol. 32. No 3 pp 347-354

During the past two years the authors have punctured the spleens of all patients with blackwater fever who have come under their control and they have correlated their findings with fairly extensive biochemical and biophysical examination of peripheral blood. They have recorded their data in tabular form and give the following summary of their observations and conclusions —

1. That there is little or no evidence of heavy malaria infection just prior to the onset of the blackwater fever in the great majority of cases.
2. That if the presence of pigment in the spleen may be taken as evidence of recent schizogony then very few cases of blackwater fever can be said to be suffering from active malaria at the time of the onset of their haemoglobinuria.
3. That the absence of pigment in the spleen may either mean that active schizogony was not going on, or that the organism possesses very variable ability to dispose of pigment rapidly.

4 That in some patients vast amounts of pigment can be found for very long periods after the initial attack of blackwater whilst in others none or only the barest traces can be found after the lapse of only a few hours from the first passage of black urine

5 That the rate at which the spleen disposes of pigment is an extremely variable factor not dependent upon the time or amount of quinine taken prior to the onset of the blackwater

6 That the reticulo-endothelial system would appear to play an important role in this pigment destruction rate

7 That the correlation coefficient between the last dose of quinine and the first passage of black urine is so significant (0.87) as to make it appear that there is more than a casual relationship between the two although quinine is by no means an essential pre-requisite since blackwater does occur after atehrin, etc.

8 That there is little difference between peripheral blood examination and spleen puncture so far as parasites are concerned the latter is a little superior so far as pigment is concerned.

9 That patients who have been in hospital and have taken a full treatment for malaria with either atehrin or quinine, sometimes go down without any warning with blackwater fever their bloods and spleens being negative for both parasites and pigment. H J

SARCINELLA (Franco) La febbre bishosa emoglobinurica ed i suoi rapporti col chunmo e la malaria. [Blackwater Fever and its Relationship with Quinine and Malaria].—*Rass. Sanitaria dell'A.O.I. Addis Ababa* 1939 July 9 Vol. 1 No 2. pp. 101-116 [39 refs.]

This is a long discussion of the well-known theories which have been advanced to elucidate the aetiology of blackwater fever. In summing up the author points to the relationship between malaria and black water even though the malaria be masked or latent and to the influence of quinine in precipitating the attacks. Blackwater is probably a malarial manifestation in persons who are for some reason predisposed and quinine acts as the determining factor precisely because it has a specific affinity for the parasites. This affinity is shown by its power of destroying the parasites if given in curative doses but if given in small doses to subjects infected with parasites particularly resistant it may act as a stimulant to those parasites after the manner of salvarsan on spirochaetes. In other words, blackwater fever may be the result of a specific exciting action of quinine on the parasites, at a certain point in the course of malaria in some instances but the author does not claim that this theory covers all cases.

Three cases are described in detail and a fourth is referred to but no experimental proof is offered in support of the author's theory.

[For a full account of the history and theories of causation of blackwater fever the reader is referred to SCOTT A History of Tropical Medicine, pp. 253-75 see this *Bulletin* 1939 Vol. 36 p. 791]

THOMAS (Rufus C.) & MILLEX (Robinson M.) A Case of Pregnancy complicated by Blackwater Fever and *Bacillus coli* Pyelitis.—*Trans. Roy Soc Trop Med & Hyg* 1939 Apr 6, Vol. 32, No 6. pp 743-750.

Details are given of a case of pregnancy complicated by blackwater fever and *Bact coli* pyelitis. The patient was a missionary's wife

who had returned to Great Britain from the Congo six weeks previously. She had had several attacks of malaria in the Congo and at least one attack of dark-coloured urine which she had attributed to quinine she had not taken quinine regularly as it upset her. On the 21st May, 1938 she was admitted to hospital with a diagnosis of accidental haemorrhage. She stated that she had had an attack of malaria the previous day for which she had taken 10 grs of quinine. She was at that time in the 36th week of pregnancy. When seen by the authors she was suffering from a typical attack of blackwater fever.

Attention is drawn to the apparent rarity of the occurrence of blackwater fever in pregnant women and it is suggested as an explanation of this that there may be in the blood of pregnant women an increase of haemolytic bodies (presumably a misprint for anti-haemolytic bodies) of sufficient amount to prevent the development of blackwater fever [See GUNTHER below] II Y

GUNTHER (Carl E. M.) Blackwater Fever following the Administration of "Atebrin."—*Med J Australia* 1938 Dec 31 25th Year Vol 2, No 27 pp 1119-1121

The author has collected from the literature a number of records of blackwater fever following the administration of atebrin. He also gives details of a case encountered by himself. The patient had apparently been under the author's observation since 1935. Her last attack of malaria was in November 1935 when she was treated successfully with quinine. On July 27th 1938 she again consulted the author. At this time she was in the fourth month of pregnancy and she was feeling fit and well but the spleen extended four fingers below the costal margin. She had had only three prophylactic doses of quinine during the previous ten days the last being on July 21st. The author ordered a course of atebrin 0.1 gm. thrice daily for five days. She had one dose on July 28th and three doses on July 29th but forgot to take her morning dose on July 30th. At 11 a.m. on that day she had a severe rigor and passed blackwater. II Y

LAFFERRE Fièvre bilieuse hémoglobinurique observée en France, révélatrice d'un paludisme à *Falciparum*. Ankylostomiasis. [A Case of Blackwater Fever observed in France in a Patient with Malaria and Ankylostomiasis.]—*Bull et Mém Soc Méd Hôp de Paris* 1938, Dec. 12. 54th Year 3rd Ser No 33 pp 1700-1702.

Clinical details are given of a case of blackwater fever. After recovery the patient had a relapse of malaria and *P falciparum* was found in the blood. The stools contained hookworm eggs. II Y

CALCUTTA ANNUAL REPORT OF THE ALL-INDIA INSTITUTE OF HYGIENE AND PUBLIC HEALTH 1937 (LAL (R. B.) Director) — [Blackwater Fever pp 23-24] [KRISHNAN (K. V.)]

In the previous year's report the author has drawn attention to certain changes in the blood and tissues met with in blackwater fever and also in malarial haemoglobinuria in monkeys. These changes include focal necrosis of the liver degeneration of the adrenal cortex an excessive production of unsaturated fatty acids a lowering of free-cholesterol and a hypofunction of the reticulo-endothelial system.

Attempts were made to correct these pathological changes and to see how far they would influence the incidence of haemoglobinuria. Treatment of monkeys with glucose ascorbic acid and cortin gave fairly satisfactory results [this *Bulletin* 1938 Vol. 35 p. 479].

During the present year this line of treatment has been extended to human beings, and seven cases of blackwater fever were treated in this manner. The cortical extract used was either a commercial preparation obtained from the Wilson Laboratories in Chicago or an extract prepared by the author following the technique of Swingle and Pfaffner. Both extracts are stated to have given equally encouraging results. The dose used was 1 cc. of the extract (equivalent to 0.1 gm. of fresh gland tissue) twice a day or oftener for about 3 to 5 days. Ascorbic acid was administered in 100 mgm. doses twice daily, glucose was administered intravenously one pint of a 5 per cent solution being given twice daily. The author states that in addition all febrile cases and those showing malaria parasites were given atabrin.

It is claimed that this line of treatment led to the following beneficial results —

"(a) A marked diminution in the intensity of haemoglobinuria. The urine cleared up within one to three days.

"(b) An increase in the quantity of urine passed. Anuria, if present, was overcome.

"(c) Rapid recovery from collapse that is invariably present and improvement in the general condition of the patient. These changes were noticed within 24 hours of the commencement of the treatment.

"(d) Complete recovery of all the seven cases treated.

[Much further evidence will be required to convince the reviewer that these results represent a *propter hoc* and not merely a *post hoc* phenomenon.]

W. Y.

CHOLERA.

PRECIS OF ABSTRACTS IN THIS SECTION

The Eastern Bureau of the League of Nations (p. 892) reports that cholera in the East was generally more than usually severe in 1937-1938. Airports must be regarded as foci of spread. The criterion for notification still remains the clinical one. The question of the El Tor vibrio is discussed. There is no general agreement on the question of the value of prophylactic inoculation.

ROBERTSON and POLLITZER (p. 893) consider that cholera during the last few years has been transported to Shanghai from the valley of the river Yuan, partly because agglutinable vibrios identical with true *V. cholerae* have been isolated from the river water. The water is contaminated from junks and in the process of transporting human night-soil for the use of farmers. Flies play a part in transmission. In control vaccination was used and chlorine to 0.9 p.p.m. was added to the buckets of the water carriers. In transfusion proper sterilization must be ensured and bicarbonate of soda may be added in cases of starvation acidosis in undernourished subjects.

READ (p. 894) has found Wilson and Blair's bismuth sulphite enrichment medium to give the best results in the laboratory in the differential isolation of *V. cholerae* and suggests a field trial.

READ *et al* (p. 895) show that both salt and organic matter are necessary for multiplication and survival of the cholera vibrio and that the presence of other organisms in equal quantity does not prevent multiplication and survival for a time.

BOSE (p. 895) found that the maximum growth of *V. cholerae* on papain-mutton agar occurs in medium in which the papain digestion is continued for 2 hours.

Of 100 strains isolated during the 1933 epidemic in Shanghai FOURNIER (p. 895) shows that all were of Heiberg's group 1 all gave positive cholera red and negative Voges-Proskauer reaction and 74 were non-haemolytic from the outset. The majority 83 were of the intermediate Hikojima type.

Certain changes in morphology metabolic activity and chemical type were found in *V. cholerae* passed through flies by LAL *et al* (p. 896) but fermentation and serological reactions were not altered.

RAYNAL *et al* (p. 896) have obtained a trichloroacetic acid extract from *V. cholerae* which precipitates with anticholera serum, is toxic and antigenic and gives allergic reactions in guineapigs sensitized to cholera.

CHECCAGGI (p. 897) uses this extract for the preparation of a rabbit anti-serum with which the cholera vibrio may be identified.

SEAL and MITRA (p. 897) have investigated the oxidation reduction potentials of *V. cholerae*.

At the Pasteur Institute Shillong (p. 897) attempts at transformation of cholera vibrios failed. Vibrios were almost universally found in natural water sources, but were never agglutinable.

KOESOMADILAGA (p. 898) shows that subpassage in white mice was only possible with *V. cholerae* if blood plate cultures were interposed between every two animal passages. Intraperitoneal injection was not successful but may be so if the El Tor vibrio is used. Blood infection may result for a period of a few hours after intraperitoneal injection or feeding with an emulsion of *V. cholerae*. Intestinal infections took place later than blood infections.

GOYLE (p. 898) advises that tests for haemolysin should be applied after incubation for 24 hours instead of for 3 days, as is usually recommended. Red cells from different animals vary in sensitivity the haemolysin is destroyed by heating and typical cholera immune serum does not neutralize haemolysin though anti haemolysin sera which are all homologous, do so.

BREUWKE (p. 899) contends that the ferments of *V. cholerae* which cause haemodigestion and the liquefaction of gelatin are separate. Haemodigestive power is lost by the El Tor vibrio if cultured on egg medium.

OTTEN (p. 899) points out that the El Tor vibrio is distinguished from *V. cholerae* not only by its haemolytic activity but because it occurs chiefly in persons with symptoms of dysentery in apparently healthy persons and in isolated cases. Investigating the so-called *V. celebicus* he shows that tests of haemolytic power should be as they are not yet carried out according to a standard method, and gives his findings. It remains to be decided whether the Celebes strain is a weakly haemolytic El Tor vibrio a strongly haemolytic cholera vibrio or an independent intermediate species.

MATRA (p. 900) found that the test of inhibition of cholera-phages by vibrio extracts with the precipitin reaction, furnishes two main groups (1) smooth cholera vibrios and the El Tor and (2) a heterogeneous group of water and other vibrios.

MERTENS and MOCHTAR (p. 901) demonstrated the want of serological unity in 32 strains of vibrios of various types.

BOSE (p. 901) uses an extract of crude mannose prepared from ivory nut shavings.

BASERJEE (p. 901) gives details of the pathological appearances in cholera noting the almost constant enlargement of the thymus and degenerative processes in the suprarenal cortex. The clinical type showing renal failure may be due to hypochloræmia rather than dehydration, and the vasomotor failure type is regarded as having an allergic basis which results in increased permeability of intestinal vessels. He suggests that histamine may be absorbed from the intestine causing the profound fall in blood pressure.

CHATTERJEE (p. 902) from post mortem examination finds that in cholera there is surprisingly little inflammatory change in the intestines, being marked in only 30 per cent. He describes the changes in various organs and the bone marrow in which eosinophils amount to 15-20 per cent.

PASRICHA *et al.* (p. 902) investigated the serum reactions of cholera patients. Agglutinins develop about the 4th day and increase H being earlier and stronger than O. They act best on the homologous strain but act also on standard Inaba strain, not on inagglutinable strains. The serological test may therefore help considerably in diagnosis.

POLEFF (p. 903) describes a method for using agglutinating serum on suspected cholera stools themselves.

PASRICHA *et al.* (p. 903) compared 5 treatments applied to patients in strictly serial order and conclude that cholera-phage gave encouraging results justifying its use as a routine measure.

The epidemic of 1937-1938 in Indo-China was introduced from China. GENEVRAY (p. 904) reports that vaccination was performed on 18,513,350 persons usually as a single dose. This was efficacious. The vibrios were of the epidemic cholera type and when freshly isolated could grow in 8 per cent sodium chloride.

GENEVRAY *et al.* (p. 904) describe an epidemic in a village in the Tonking delta. Its origin was obscure but vibrios of the Inaba type were found in two ponds. Vaccination was carried out extensively and to this the authors attribute the sudden end of the epidemic which occurred.

VOGEL and RIOU (p. 905) however have examined the results of vaccination in Tonking and see no advantage in it. Cholera may disappear spontaneously and may attack vaccinated and non vaccinated communities indiscriminately with little difference in mortality.

LEAGUE OF NATIONS. HEALTH ORGANISATION	EASTERN BUREAU
SINGAPORE. ANNUAL REPORT FOR 1938.	(Disease Incidence)
Cholera in Countries & Ports. pp. 27-60	With 20 graphs &
5 maps [18 refs.]	

Under the heading Cholera in Countries it is noted that cholera in British India has been more severe than the average for the preceding quinquennial period. Cholera in the East generally during

1937 and 1938 seems to have been more than usually severe. In China and French Indo-China it is understandable that the refugee influx into certain territories would be a powerful factor in epidemicity. As in the case of plague airports must be added to seaports as foci of special or even greater danger for the spread of cholera. Notifications from airports in British India were received from Allahabad, Calcutta, Delhi and Jodhpur from Hanoi in French Indo-China and from Hankow in China. Calcutta among the sea ports is credited with having been infected as usual with cholera throughout the year. In connexion with this statement of unenviable invariability for the Hoogly Delta it is interesting to learn that the Commissioner in charge of League of Nations Anti Epidemic Unit 2 suggests that cholera in Central China is endemic.

Many interesting points are raised in this report which are also of the highest importance. The Cholera Commission considered that the criterion to be adopted in notifying proved cases of cholera under the 1926 Convention still remained the clinical one while at a subsequent meeting the Commission expressed the opinion that from the point of view of the sanitary measures to be taken neither the El Tor nor the non agglutinable vibrios can be considered as comparable to the cholera vibrio of Koch. This reference to the El Tor question occurs in the report in a commentary at the end of the paragraph on Cholera in Netherlands India. It has reference to what it has been suggested should be called *Vibrio celebicus* regarded as an El Tor type although with somewhat ill defined characters. A map is also given showing location of El Tor cases in Celebes [See this Bulletin 1939 Vol. 36 pp 374-375].

Another indirect reference to El Tor is the quotation of the view of DOORENBOS on the factors favouring the conservation and regeneration of the cholera vibrio. It has been found at Tor that while vibrios often disappear spontaneously from healthy carriers such is not the case with those carriers who are suffering from dysentery.

Prophylactic inoculation against cholera comes in for a somewhat mixed treatment. Discussions on this point which took place at the meeting of the Advisory Council of the Eastern Bureau at Hanoi and subsequently showed that no unanimity existed in regard to its value during an epidemic or to quote from opinions nearer home TOPLEY and WILSON refer to the difficulty in assessing the value of cholera inoculation in reports which have been published. POLLITZER working in the midst of epidemic cholera in China refers to the distrust which some observers have of statistics tending to prove the value of anti-cholera vaccination and suggests that what is needed is discrimination in regard to statistical evidence rather than general scepticism. Exact interpretation of his opinion would depend largely on the meaning conveyed by the word discrimination.

ROBERTSON (R. Cecil) & POLLITZER (Robert). Cholera in Central China during 1938—its Epidemiology and Control—*Trans Roy Soc Trop Med & Hyg* 1939 July 23 Vol. 33. No 2 pp 213-232. With 1 map & 17 figs. on 4 plates.

An account is given of the working of the English-speaking second unit of the League of Nations Epidemic Commission to China in the provinces of Hunan, Hupeh and Kiangsi during 1938 which was a

least 1/5 000 after 2 hours at 37°C. with the laboratory serum. All were found to belong to Heiberg's group I (mannose and saccharose positive, arabinose negative) all gave a positive cholera red and a negative Voges-Proskauer reaction. Out of the 100 strains 74 were non-haemolytic from the outset and 26 had shown some degree of haemolytic action on suspensions of sheep erythrocytes. Any haemolytic property possessed by freshly isolated strains was lost after some months. Each of the strains was tested serologically after saturation of an Inaba Hikojima and Ogawa serum by the heterologous type organisms, and showed that 4 83 and 2 strains were original Inaba, intermediate Hikojima and variant Ogawa respectively. One strain was unclassifiable. This confirms the finding for the epidemic of 1933 where also the intermediate type of vibrio was highly preponderant.

LAL (R. B.) GHOSAL (S. C.) & MUKHERJI (B.) Investigations on the Variation of Vibrios in the House Fly—*Indian J. Med. Res.* 1939 Jan. Vol 28 No. 3 pp. 597-609

These investigations were undertaken in order to determine whether changes occurred in cholera vibrios after passage through flies, such as might give colour to the view that they existed in a form which was not readily recognizable in an endemic region or in an inter-epidemic period. From the epidemiological point of view this matter is of considerable importance. Great precautions were taken to breed out flies which could be said to be free from infections. This much was certainly effected. The insects were invariably found to be free from contamination with bacteriophage or with organisms even remotely resembling *cholerae*.

The experiments have on the whole, been indecisive and no conclusions have therefore been drawn at this stage. The results may be summarized—(1) Certain changes are described in the morphology of the vibrios and their colonies but no change in fermentation reactions and no change of "O" serological type. (2) Changes in metabolic activity and in chemical type as determined by the methods employed by LIXTON were found in the case of many of the strains recovered from flies.

RAYNAL (J.) LIEOU (Y. Ch.) & FEISSOLLE (L.) Propriétés biologiques d'un extrait trichloracétique (antigène complet) obtenu à partir du vibron cholérique [Biological Characters of a Trichloroacetic Cholera Extract.]—*Rev. d'Immunologie* Paris 1939 July Vol 5 No 4 pp 317-320

Previous work had shown that a complex unstable compound consisting of polymaccharide and phospho-fatty acid could be extracted with trichloroacetic acid from many gram-negative bacteria. BORVIX and MESROBIANU consider that this represents both endotoxin and somatic antigen. The same technique of extraction has been followed by the authors in the case of the cholera vibrio and a pale yellow liquid obtained. It possesses precipitating action on anticholera serum, toxic action on mouse and rabbit, antigenic and immunizing power in the rabbit and intradermic allergic action in guinea-pigs sensitized intraperitoneally with living cholera vibrios. CHECCACCI (L.) Ricerche sulla struttura antigenica del vibrio colerigeno. Nota I. Studio del cosiddetto antigene glucidico in rapporto alla classificazione di Gardner e Venkatraman [Antigenic Structure of the Cholera Vibrio Glyco-lipoid Antigen Constitution and Classification.]—*Boll Istituto Sieroterap Milanese* 1939 June Vol 18. No 6 pp 391-407 [75 refs]
German summary

BORVA and MESROBEANU's method of obtaining a soluble extract of cholera vibrios by means of trichloroacetic acid has been followed and the object of this research is the elucidation of the antigenic properties of this complex phospho-fatty compound with polysaccharide. It has in all probability been identified with the specific O antigen which forms the basis of the classification of vibrios into subgroups by GARDNER and VENKATRAMAN. Intravenous inoculation of the extract in the rabbit produces a serum which specifically agglutinates and precipitates homologous vibrios in high titre and fails to agglutinate except in low titre vibrios belonging to other serological subgroups and the cholera like vibrios. It is usable for the identification of the cholera vibrio in the same way as an O serum with this difference that it manifests its specificity either towards living vibrios or to vibrios killed at 100°C for two hours.

SEAL (S C) & MITRA (B N) Oxidation-Reduction Potentials of Vibrio cholerae and Related Organisms—*Indian J Med Res* 1939 Jan. Vol 26 No 3 pp 625-630 With 2 graphs & 1 plate

An elaborate combined potentiometer and pH meter was used. It was found that the average potential curves of the organisms belonging to different chemical groups were different from one another. The pH values follow very closely the fall and rise of electrode potential curves. These curves under the conditions of experiment show a fall to a minimum in about 6 hours and then a gradual rise to a maximum in about 30 hours. The fall corresponds to the so-called lag phase of the growth of the organisms and is characterized by having low pH in the medium.

SHILLONG KING EDWARD VII MEMORIAL PASTEUR INSTITUTE AND MEDICAL RESEARCH INSTITUTE TWENTY FIRST ANNUAL REPORT FOR YEAR ENDING 31ST DECEMBER, 1937 [AHUJA (M. L.) Director] pp 6-10—Cholera Enquiry under the Indian Research Fund Association.

With the closure of the Field Unit at Habiganj in 1937 cholera enquiry at the Institute has been directed to purely laboratory research. These researches are given in some detail and some of them have been already published. Attempts at transformation of agglutinable cholera vibrios to non-agglutinable forms are a fertile subject of research and an endeavour was made to change the Inaba rough strain to the Rangoon Rough which is a smooth but non-agglutinable vibrio of a different type often isolated from cases of cholera. The experiment failed. Other experiments on transformation were directed to keeping an agglutinable vibrio in raw water but the evidence that it changed into an non-agglutinable vibrio was quite unconvincing. The duration of life of the non-agglutinable vibrio as such was short the maximum period of life being 7 days.

Enquiry into the incidence and characters of vibrios in natural water sources extended to 77 samples 54 from tanks and 23 from rivers. These yielded 21 organisms of which 2, 2, 7 and 10 were placed in HÄNDEL'S groups I II III and IV respectively. No example of groups V and VI were isolated. Study along these lines showed that "vibrios are almost universally present in natural water sources" but that "in no instance was an agglutinable vibrio isolated."

Publication of the work on papain-casein medium as a substitute for papain digest mutton in the propagation of bacteriophage has already been abstracted [this *Bulletin* 1899 Vol. 36 p 377] W F H

KOESKOMADILAGA (R. M. R.) Experimenteële cholera-infectie bij witte muizen [Experimental Cholera Infection in White Mice]—*Geneesk Tijdschr v Nederl Indië* 1899 June 27 Vol. 79 No. 23. pp. 1602-1622. [18 refs.]

Much argument has centred around the question whether cholera vibrios are to be found in the blood stream for a time at least, and whether they thus reach the internal organs. Most of the earlier trials negatived this occurrence and it was only later that SANARELLI especially put forward the contention of entry of the cholera vibrio via the fascial ring of lymphoid tissue into the lymphatic and then the blood stream. His contention was that the acidity of the gastric juice and the gastric mucosa constituted an almost absolute barrier to passage of the cholera vibrio. The enterotropic character of the cholera organism was pronounced and independent of the mode of administration whether oral, subcutaneous, intraperitoneal or intravenous. The present author in his own experiments, which are purely animal, has made a departure from custom in using white mice as test animals and he has found them perfectly suitable. He introduced vibrio suspensions by tube into the stomach placed culture material on the tongue and fed his animals with bread soaked in a suspension of vibrios. The results are given with a certain amount of caution, owing to the small number of animals used. He has shown that —

(1) White mice are suitable animals for testing cholera vibrios. (2) Subpassage was proved possible from animal to animal with the El Tor but not with either of the two cholera strains used. Continuity of passage could, however be attained with cholera also if a blood plate culture was interposed between every two animal passages. Subpassage was made from the spleen of the animal. (3) Intraperitoneal injection of El Tor vibrios, after they had been passaged 5 times killed 18 of 30 animals within 24 hours. cholera vibrio injection was without result, except in one case for 20 animals. (4) Intraperitoneal injection of vibrios and feeding with vibrio suspension gave rise to blood infection in 10 minutes and disappearance again after 6 to 10 hours. No general blood infection followed deposition of culture on the tongue or feeding with soaked bread. (5) Intestinal infections took place later than blood infection. W F H

GOYLE (Amar Nath) Observations on Haemolysis by Vibrios.—*Indian J. Med Res* 1899 Jan. Vol. 26 No. 3 pp 611-624.

The vibrio strains tested were all of haemolytic type and their potency as regards production of haemolysin was determined after 2 and 4 hours incubation and thereafter daily up to 10 days. Some

interesting variations of potency were manifest in this series but all the strains showed some degree of haemolytic power after 4 hours. Continued incubation might show diminution of potency and this leads to the conclusion that tests for haemolysin should be applied after 24 hours incubation and not—as is usually recommended—after 3 days. A number of interesting features were determined for the vibrio haemolysin by the quantitative experiments of the author such as that—(1) erythrocytes of different species of animals show varying sensitiveness to haemolysin greatest in the guinea pig about the same in goat sheep and rabbit and least in pigeon monkey horse and man. No correlation could be found between cholesterol or lecithin content and haemolytic sensitivity (2) The haemolysin was filterable in spite of some adsorption in the process. It is completely destroyed in 10 minutes at 56°C and the potency of cultures or filtrates is lost if kept at 37°C. Cold storage preserves haemolysin with or without the addition of 0.5 per cent phenol (3) Anti-haemolysin sera appeared all to be neutralizing and of homologous nature but a typical cholera vibrio immune serum failed to show any neutralizing action

BEEUWKES (H) Ueber die proteolytischen Fermente des *Vibrio cholerae* und des *Vibrio El Tor* [The Proteolytic Ferments of the Cholera and El Tor Vibrios].—*Zent f Bakt I Abt Orig* 1939 Feb 20 Vol. 143 No 3/4 pp 220-225 With 2 figs [10 refs.]

The property possessed by the cholera vibrio of haemodigestion, where a green transparent sharply defined zone develops around colonies and the property of liquefying gelatin have a certain parallelism which might signify that they were due to one and the same ferment. It has been objected to this view that the properties of all ferments may be influenced by much the same factors and that a parallelism of variation does not justify the conclusion as to identity. The author himself contends that the two ferments are distinct and uses two different cholera strains for a demonstration that they did not individually behave according to expectation in their action on gelatin and on blood, as they should have done if the ferments concerned were identical.

In the same research 4 El Tor strains were investigated for their haemodigestive and gelatin-liquefying characters. The strains were subcultured on agar and preserved on a special egg medium. Liquefying power was estimated by means of the viscosimeter. It was found that the El Tor strains cultured on blood agar exhibited greater liquefying and digesting power than was the case with strains kept on the egg medium. On this latter medium haemodigestive power was lost

- i. OTTEN (L.) Het cholera El Tor probleem [The Cholera-El Tor Problem].—*Geneesk Tijdschr v Nederl Indië* 1939 Mar 14 Vol. 79 No 11 pp 642-654 [48 refs.]
- ii. — The Cholera-El Tor Problem.—*Meded Dienst d Volksgezondheid in Nederl Indië* 1939 Vol. 28. No 1 pp. 13-21 [46 refs.]
- i The El Tor vibrio problem has been raised anew with the isolation in a small epidemic by DR. MOOR of a haemolytic vibrio. In this

epidemic the patients all had typical cholera symptoms. Now it has to be remembered that the original El Tor vibrio although morphologically and serologically identical with the cholera vibrio makes its appearance for the most part in individuals with symptoms of dysentery in apparently healthy individuals and in the sporadic non-epidemic cholera case. These are features pertaining to the El Tor vibrio as well as its haemolytic activity which so far distinguish it from the cholera vibrio. The epidemic in question occurred on the island of Celebes and the vibrio isolated has been named provisionally *V. celebes*. Otten has examined the characters of this organism in detail and has looked closely into the technique for proving a vibrio to be haemolytic. It is remarkable that the technique for establishing haemolytic character differs rather widely in different hands. Otten has investigated such points as age of bouillon culture, duration of incubation for the production of haemolysis and mode of addition of the testing blood. His conclusions are —

1 (a) The Celebes strains show haemolysis constantly within 24 hours although much more weakly than the typical *V. El Tor* the formed haemolysin is more labile and is absent from 5-day bouillon cultures. (b) This haemolysis is not demonstrable in 3-day bouillon cultures or in 2-day peptone water cultures when culture and blood are incubated together for only 2 hours at 37°C.

2 (a) These phenomena may however be exhibited even by cholera strains, although not regularly and much more weakly than by the Celebes strains the formed cholera haemolysin is even still more labile. (b) No haemolysis occurred, however in cholera bouillon cultures even after continuous incubation at 37°C. if the added blood was first allowed to sink before inoculating the culture.

3 It is very desirable that the haemolysis test should be carried out according to a standard method.

It remains to decide whether the Celebes strain is to be regarded as a weakly haemolytic El Tor vibrio a strongly haemolytic cholera vibrio or an independent species with a position intermediate between the other two.

ii This is a version of the above written in English. IV F H

MAITRA (N. N.) On Inhibition of Individual Types of Cholera-Bacteriophage by Vibrio Extracts.—*Indian J. Med. Res.* 1939 July Vol 27 No 1 pp 41-49

It has been shown previously that extracts of typical cholera and allied vibrios were capable of inhibiting cholera-phage lytic action and that 3 groups of these vibrio strains could be differentiated by the application of these inhibition tests. The present work continues this study and combines it with precipitin reactions. According to previous work it was also found that phage inactivating power is destroyed by the addition of homologous antiserum concurrently with the appearance of specific precipitin reaction. The work now undertaken shows that (1) The test of inhibition of cholera-phages by vibrio extracts, together with the precipitin reaction of these extracts, furnishes two main groups (a) typical smooth cholera vibrios and the El Tor vibrios belonging to "O" subgroup I (b) a heterogeneous group of water and other vibrios. The inhibition and precipitin reactions would seem to depend on a common factor related

to the complex polysaccharide receptor of the cholera vibrio but not to the polysaccharide type as determined by chemical analysis

H F H

MERTENS (W H) & MOCHTAR (A) An Investigation of Vibrios in the Netherlands East-Indies.—*Indian J Med Res* 1939 July Vol. 27 No 1 pp 51-63 [13 refs]

Out of 510 vibrio strains isolated from 20 444 samples of faeces and water 32 were found to agglutinate with an HO cholera serum. These 32 strains were represented by 15 from non-cholera patients 16 from healthy stools and 1 from water They formed along with 10 cholera and 10 El Tor and *V. celebica* control strains the material for study Special anti-sera were made to individual strains and it was found that 17 such sera were still insufficient to classify the 32 strains thus indicating their want of serological unity The conclusions were also reached that anti-O cholera sera are more specifically diagnostic than OH sera and that HEIBERG's fermentative classification is insufficient if used alone

H F H

BOSE (Sarashipada) Note on the Preparation of an Unpurified Mannose Solution for Bacteriological Use.—*Indian J Med Res* 1939 July Vol. 27 No 1 pp 73-74

Mannose a very expensive sugar is invaluable for the classification of vibrios by fermentation methods. The author has obtained an extract of crude mannose from ivory nut shavings—a waste product in button manufacture—which gives the same fermentation results as the pure sugar Three pounds of ivory nut shavings treated by the method described yielded 620 gm. mannose

BANERJEE (Dhirendra Nath) Outlines of the Pathology of Cholera.—*J Indian Med Assoc* 1939 Apr Vol. 8 No 7 pp 391-395 With 4 figs. on 1 plate [37 refs]

The pathological appearances of some of the organs of the body in cholera cases is referred to in useful detail In the small intestine congestion of both serous and mucous surfaces is a marked feature but whereas the peritoneal coat used to be described as dry this appearance is now seldom seen provided the patient is not allowed to die of dehydration. Peyer's patches especially but also the solitary lymphoid follicles appear prominent. On microscopic examination the characteristic features in the small intestine are extreme necrotic change in the intestinal epithelium distension of the capillaries profound subepithelial oedema and distension of gland tubules with cholera vibrios. It seems probable that the destruction of the epithelial lining of the small intestine is the cause of the great dramatic change which has been almost constantly noted is enlargement of the body fluid and salts into the lumen of the intestine. A pathological change which has been almost constantly noted is enlargement of the thymus possibly because it is a lymphoid organ. On the other hand the spleen is not enlarged and may appear small and wrinkled if death takes place during the stage of dehydration. Reference is made to the pathology of the suprarenals because of the suggested adrenal insufficiency as a factor in the production of the syndrome of cholera. Degenerative changes are to be found in the suprarenal cortex.

GENEVRAY (J) Le choléra en Indochine en 1937-1938. [Cholera in Indo-China, 1937-1938.]—*Bull Office Internat. d'Hyg Publique* 1939 June Vol. 31 No. 6 pp 1024-1040 With 1 chart & 1 folding map

Cholera tends to appear in Indo-China in sharp epidemics with long intervals between. The epidemic of 1928 was the most fatal ever recorded but no cases of cholera have been recorded in Cambodia and Cochm-China since 1934 and in Annam since 1934. Neither Laos nor Tonking have had any cases for 10 years. The present epidemic was introduced from China. Where a country has such an indented coast line and so many creeks, seaport quarantine is almost certain to be ineffective. Water carriage seems to have played but little part in transmission which was from case to case. Although the epidemic was not a severe one in its extent it had a high mortality of 60 to 80 per cent. The symptoms were of ordinary type.

Vaccination measures were applied on a large scale and 13,513,350 vaccinations carried out. Although the majority of these were of the single dose type it is considered that they were efficacious. When full vaccination was carried out, as in the case of administrative and military groups, it gave complete protection from cholera.

Some interesting laboratory investigations were conducted on the vibrios, which appear to have been very uniformly of the epidemic cholera type. The practical superiority of the use of O sera was established. No pseudocholera vibrios were isolated and on only two occasions were cholera vibrios isolated from water. Bacteriophage however was isolated from ponds around which cases of cholera had occurred.

It was found that the freshly isolated cholera vibrio is resistant to high concentrations of salt and can grow in an 8 per cent. sodium chloride. A culture medium which utilized this property was tried out with success and with great saving of time and work. [See also this *Bulletin* 1938, Vol 35 p 742, and 1939 Vol 36 p. 378.]

GENEVRAY (J) BRUNEAU (J) & SEYERLICH (A.) Etude d'une épidémie de choléra dans un village du delta Tonkinois. [A Cholera Epidemic in a Tonking Delta Village.]—*Bull Soc Path. Exot.* 1939 Mar 8 Vol 32 No 3 pp 232-267 With 2 figs

The interest of this epidemic lay in its sudden occurrence in a small community of not more than 1,200 persons, when no cholera had been notified in the Province for 4½ months and none in the whole of Tonking for 1½ months. It was all over in 15 days but consisted of 60 cases with 52 deaths. The vibrios isolated from the stools in the course of the epidemic were of Inaba type. Other interesting points in connexion with this epidemic were that the only well of the village gave no cholera but vibrios with all the Inaba characters were isolated from two village ponds. Then also there were no carriers found among individuals in the households of patients or even among the cured patients themselves. No trace of bacteriophage could be found to account for the sudden termination of the epidemic or the sudden disappearance of cholera from the village ponds. As 960 vaccinations were performed almost immediately the epidemic broke out the authors conclude that it was this measure which brought the outbreak to so sudden a finish.

VOGEL (E) & RIOU (M) Les maladies épidémiques endémiques et sociales dans les colonies françaises pendant l'année 1937 Choléra. [Disease in French Colonies in 1937 Cholera].—*Ann de Méd et de Pharm Colon* 1939 Apr Vol 37 Supplement pp 270-286

An account of the ravages of cholera in each of the French colonies is given in some detail. It is a little unusual to find a reasoned statement in an official report which is adverse to the almost universal acceptance of the efficacy of vaccination. The medical officer of the province of Namdinh in Tonking in which 764,500 vaccinations were performed has seen spontaneous arrest of cholera in non vaccinated villages and its recrudescence in vaccinated villages. He considers also that epidemic cholera came to an end in non-vaccinated China at the same time as it did in vaccinated Tonking. In the province of Annam little difference in mortality is manifest between vaccinated and non-vaccinated villages while in the province of Vinh where cholera ceased in the primary focus after a massive inoculation of the population it was found that on recurrence it ravaged indifferently vaccinated and unvaccinated villages. A wise remark on vaccination made in this report is that It is however necessary to be very circumspect in interpreting the results in a favourable as well as an unfavourable sense. H F H

JOURNAL OF THE ASSOCIATION OF MEDICAL WOMEN IN INDIA. 1939
May Vol. 27 No 2 pp 145-147 The Cholera Danger Useless
Vaccines on the Market. Necessity for using Genuine Vaccine.

There is no doubt of the existence of very numerous cholera like organisms and much time and care has been devoted to defining the characters of the true cholera vibrio. As there is some possibility that the latest research work on the subject is not known to all purveyors of cholera vaccine three of the main Government laboratories have undertaken to issue suitable strains to laboratories and commercial firms for the preparation of vaccine. CALCUTTA ANNUAL REPORT OF THE CALCUTTA SCHOOL OF TROPICAL MEDICINE AND THE CARMICHAEL HOSPITAL FOR TROPICAL DISEASES 1938 [CHOPRA (R. N.) Director].—[Cholera [DEMONTE (A. J. H.)] pp 121-132. With 2 charts.]

EPIDEMIC DROPSY AND DEFICIENCY DISEASES

PRÉCIS OF ABSTRACTS IN THIS SECTION

RAY and GANGULY (p 907) have established a normal in the urinary constituents of Bengalee subjects. Compared with Americans and Europeans this shows that the average diet is poor in protein. They followed up this work by investigations in epidemic dropsy in which

the urine shows increased uric acid reduced chlorides and reduced inorganic phosphorus, the latter constituting a good diagnostic sign.

LAL (p 907) describes an outbreak of epidemic dropsy confined to a group of servants who messed together. Others in the household were not affected, though in close personal contact. All available evidence incriminates mustard oil, but the toxic component is not known. From careful work, LAL, AHMAD and ROY (p 908) conclude that allylisothiocyanate present in mustard oil is not responsible for the symptoms of epidemic dropsy.

LAL and ROY (p 909) give details of 8 outbreaks. They tested mustard oil used in 3 of these, using sound oil as control and volunteers using two of these oils, but not the third, developed epidemic dropsy. This evidence tends to confirm the mustard oil theory but CHOPRA *et al.* (p 909) produce evidence that symptoms indistinguishable from those of epidemic dropsy can be produced in man by the consumption of mustard oil to which has been added oil from the seeds of *Argemone mexicana* but not by mustard oil alone. The toxic principle is destroyed by heating to 240°C. and the argemone seeds bear some resemblance to those of the mustard plant. LAL *et al.* (p 910) have elaborated two chemical and two physical tests which indicate disease-producing mustard oil. The seeds of *Argemone mexicana* impart the physical and chemical properties of toxic oil to mustard oil and from argemone oil and toxic oil, but not from pure mustard oil, a white crystalline substance has been isolated which responds to the differential tests. This will be tested for toxicity.

SINGHA (p 911) describes the symptoms of an anomalous type of epidemic dropsy in which an acute cardiac crisis, without dropsy occurs. Cyanosis and dyspnoea occur and the prognosis is bad. Treatment is unsatisfactory.

In nutritional oedema SHUKRY *et al.* (p 912) found hypochromic anaemia hypoproteinaemia, reduced blood cholesterol and rise in chloride content of the oedema fluid—conditions found in animal experimental starvation oedema.

Vitamin deficiency, particularly vitamin C is regarded by TROLLE (p 912) as the principal cause of a syndrome seen in African children characterized by severe anaemia, loss of pigment especially in the hair oedema and bleeding from the gums. Ankylostomiasis is often present and must be treated, but the essence of treatment is a generous diet. VAN DAELE (p 913) in the Congo describes the condition Buaki which resembles this syndrome in many respects, though in Buaki there is no stomatitis. It responds to the administration of a well balanced mixed diet, and is thought to be due to excess of carbohydrate and lack of protein and vitamins. POUHIN (p 913) describes a syndrome of oedema, sometimes with nervous symptoms, in Morocco. The diet of the inhabitants is low in animal protein, and the most successful treatment is the addition of meat and lemons.

VIDAL (p 914) describes a mixed avitaminosis in children showing oedema of the legs cyanosis, inflammation of the lips and gums and erythema. Gastro-intestinal disturbance is common. The condition resembles pellagra in some respects and other deficiency diseases of children. Ankylostomiasis is not a factor.

DEBDAS (p 914) records children who after long periods of diarrhoea developed purpuric symptoms and calls attention to the necessity of administering orange juice to ensure a sufficient supply when diet is restricted and elimination in frequent stools, is rapid.

RAY (S N) & GANGULY (R.) Urinary Composition of Normal Bengalee Subjects.—*Indian Jl Med Res* 1938. Oct Vol 26 No 2. pp 459-463 [13 refs.]

With a view to accounting for urinary conditions and constituents in disease it is important to have a standard which may be regarded as normal for comparison. The authors have tried to establish this in Bengalees by analyses of 24-hour specimens from middle class Hindu Bengalees male and female between the ages of 16 and 28 giving a history of good health during the preceding two years. In the original paper a table is given comparing the findings with those in Americans and Europeans. The two latter show closely approximating results one to the other but in certain particulars differ markedly from the Bengalee analyses. Thus urea excretion in the Bengalees was only 4.3 gm. in 24 hours (average of about 50 persons) as compared with 31.5 and 30 in Americans and Europeans respectively and total nitrogen 4.83 as compared with 16.8 and 16.0 inorganic sulphates were 0.65 gm. as compared with 3.27 and 2.92 gm. Calcium excretion was also low 0.06 as compared with 0.17 and 0.15 respectively. It is curious to note that the excretion of uric acid 0.7 gm. is equal to that of the European and higher than that of the American 0.64 while chloride excretion (17.4) is higher than in Americans (10-15 gm.) Neutral sulphates were the same 0.18, 0.18 and 0.17 respectively and ethereal sulphates 0.1, 0.19 and 0.22. These figures indicate that the average Bengalee diet is poor in food protein about 35 gm of protein only per day well below Chittenden's minimum.

RAY (S N) & GANGULY (R.) Observations on the Metabolic Activity of Patients suffering from Epidemic Dropsy Part I. Urinary Composition of Epidemic-Dropsy Patients.—*Indian Jl Med Res* 1938. Oct Vol 26 No 2. pp 465-468

Following up their analyses of normal urinary constituents in Bengalees (see above) the authors have turned their attention to pathological conditions and deal first with epidemic dropsy. The chief alterations as shown in a table were an increase of uric acid excreted 0.94 as compared with the normal 0.7 gm. a reduction by about one third in chloride (11.4 as compared with 17.4) and a reduction of inorganic phosphorus to one-sixth 0.11 as compared with normal 0.68. The ethereal sulphate was not altered a fact which militates against the idea that the cause is an intestinal bacterium or bacterial toxin at all events of a phenolic nature.

The increase of uric acid in epidemic dropsy had been previously noted and is ascribed to disturbance of the cell nuclei. The low excretion of inorganic phosphates may be utilized in the authors' view as a sign of diagnostic value in suspected cases. The lowered output of chlorides is due to retention for the diet was the same this is corroborated by finding increased concentration of chlorides in the blood during an attack of epidemic dropsy.

LAL (R B) Further Studies in Epidemic Dropsy.—*Calcutta Med Jl* 1938 Sept. Vol 34 No 3. pp 169-182. With 2 plans & 3 figs. on 2 plates.

CALCUTTA MEDICAL JOURNAL. 1938. Sept. Vol 34 No. 3 pp 218-221.—The Epidemic Dropsy Problem.
Dr Lal who is probably the best authority on this condition at the present day having done much experimental work and epidemiological

resembling those of epidemic dropsy following consumption of mustard oil adulterated with *sialkata* or *katakar* oil argemone oil [see this Bulletin 1927 Vol 24 p 238] and two years later KAMATH reported the Ganjam outbreak where *odismari* seeds were implicated [this Bulletin 1929 Vol. 28 p 355]. More recently the work of LAL, ROY and GHOSAL has thrown fresh light on the question [this Bulletin 1938 Vol. 35 p 312].

In oils obtained from houses where there had been cases of epidemic dropsy positive reactions for argemone oil were obtained, and *odismari* seeds were shown to be seeds of *Argemone mexicana*.

Volunteers were divided into three groups. For one the food was cooked in pure mustard oil to which known quantities of argemone oil were added for the second the food was cooked in samples of oil giving argemone oil reactions and implicated in natural outbreaks of the disease the third group had a similar diet but the food was cooked in mustard oil giving no reaction for argemone oil. The results of the experiments are given in two protocols. Some of the symptoms of the disease appeared in those receiving argemone oil which seems to have a cumulative effect provided a certain quantity is taken the symptoms appear after an interval though consumption of the oil is stopped. Its toxic principle is destroyed by heating to 240°C. not at 150°C.

The authors conclude that ingestion of the oil expressed from the seeds of *Argemone mexicana* can produce the symptoms of epidemic dropsy, but

Whether the condition produced is identical or not with the naturally-occurring epidemic dropsy cannot be definitely said at present, but there is no doubt that the use of oil containing argemone oil is harmful to man. There appears to be little doubt that consumption of adulterated oil produces symptoms which cannot be distinguished from those encountered in the naturally-occurring disease.

From the evidence available it appears that the adulteration of mustard oil with argemone oil may or may not be intentional on the part of those who grow the mustard plant, or of those who express or sell the oil. The plant *Argemone mexicana* is widespread, its seeds bear a superficial resemblance to mustard seeds and may be harvested along with them. It is possible that, because oil can be obtained from the seeds of this plant, efforts are not made to exclude these seeds in the harvesting of mustard seeds.

H H S

LAL (R B) MUKHERJI (S P) ROY (S C) & SANKARAN (G)
Investigations into the Epidemiology of Epidemic Dropsy Part VIII. Studies on the Nature and Origin of Certain (?) Toxic Substances Present in the Supplies of Mustard Oil associated with Outbreaks of Epidemic Dropsy—*Indian J. Med. Res.* 1939 July Vol 27 No 1 pp. 207-224 With 7 figs on 2 plates.

In pursuance of their work on epidemic dropsy the authors on the assumption that the cause is to be found connected with the mustard oil used carried out investigations to determine the offending constituent. Their first step was to discover some tests which would distinguish sound from disease-producing oil. They found two chemical and two physical tests. The chemical are (1) The Nitric Acid test. When a little of the oil is vigorously shaken with an equal quantity of concentrated HNO_3 , in the case of toxic oil a brownish red colour develops in the bottom acid layer. (2) The Cupric Acetate

test If a mixture of the oil acidified with glacial acetic acid and 3 per cent solution of cupric acetate be heated in a water bath for 15 minutes, in the case of a toxic oil a precipitate forms and the colour of the watery layer changes from blue to green. The physical tests are (1) Spectroscopic Whereas the general nature of the spectrum is the same in toxic and non toxic, the latter show a broad absorption band between 2,900 and 2,600 A.U. with maxima near 2,750 (2) Fluorescence on exposure to ultra violet rays absent in sound oils

Results of these tests are given in the subjoined table —

Test		Epidemiological history and toxicity positive (class I)	Epidemiological history and toxicity negative (class II)
Nitric acid test	{ Positive	21	2
	{ Negative	2	21
Cupric acetate test	{ Positive	31	0
	{ Negative	2	23
Fluorescence test	{ Positive	22	11
	{ Negative	1	12

The authors next set out to determine whether the poisonous effects were due to deteriorated mustard seeds to adulteration of the oil or adulteration of the seeds They found that seeds of *Argemone mexicana* which resemble the black mustard seed *Brassica napus* impart the physical and chemical properties of toxic oil to mustard oil, and either accidentally or by deliberate adulteration these find their way into stocks of mustard seed and the expressed oil is present in sufficient amount in the final product to cause the symptoms observed in the outbreaks of epidemic dropsy Further from oil of *Argemone mexicana* and from a proved toxic oil (but not from pure mustard oil) a white crystalline substance has been isolated which responds to the differential tests. Study is to be undertaken to determine whether this is the actual toxic substance.

H H S

SINHA (B C) Some Special Clinical Aspect of Epidemic Dropsy and the Limitations of its Treatment.—*Trans Med College Re-Union Calcutta* 1938-39 Vol. 2. pp 81-84

The author has lately had under observation patients suffering from epidemic dropsy of an anomalous type in short epidemic dropsy, without dropsy but with acute cardiac crisis. The first observed symptom is usually intense dyspnoea of sudden onset but enquiry reveals cases of epidemic dropsy in other members of the family. Cyanosis is present but not very marked. All show some degree of cardiac enlargement, with more or less tumultuous action but without irregularity the pulmonary second sound is accentuated and there may be a soft systolic murmur at the apex Pulse is 100-140 regular of low tension blood pressure 100-130 mm systolic, 50-70 diastolic. The liver is enlarged and tender The prognosis is grave four patients referred to in this article all died within 3-4 days

The cause of the dyspnoea is discussed, whether central or due to impending ventricular failure. Treatment is very unsatisfactory and disappointing. Patients gain some ease by being propped up in bed and by injections twice daily of 1 cc. luminal and 1/100 grain of atropin. Venesection and abstraction of 8-10 oz. daily for 2-3 days may relieve but not after the first few days. Inhalation of oxygen gave no relief. Ephedrine and adrenaline were without effect, digitalis and strophanthine made no impression when there was tachycardia. Glucose proved useless. Sleeplessness was a troublesome symptom which was unrelieved by the usual hypnotics. H H S

SHUKRY (H.) MAHDI (M. A.) & EL GHOLMY (A. A.) Nutritional Oedema in Children in Egypt.—*Arch Dis in Childhood* 1938. Sept. Vol 13 No 75 pp. 254-257 [Summary appears also in *Bulletin of Hygiene*]

The authors have investigated eighteen cases in Egypt, children ranging in age between $1\frac{1}{2}$ and 10 years, suffering from gastrointestinal disorder with oedema. Theoretically oedema develops when (1) the colloid osmotic pressure of the plasma becomes less than that of the cellular fluid (2) there is increased permeability of capillary endothelium to salt and water and (3) abnormal mechanical forces are acting.

In all but three the total serum protein was 4.5 per cent. or less, i.e. the critical level of experimental oedema. The chlorides showed an increase of 120 mgm per cent or more in one case 482 mgm difference between the blood and oedema fluids, instead of the usual 50 mgm per cent higher in the cellular spaces. A table of detailed findings demonstrates an almost constantly present hypoproteinaemia and the increased chloride content of the oedema fluid. By experiments on dogs the authors concluded that the return of serum protein to normal level is probably determined not only by adequate diet but also by the time needed for restoration of the activity of the liver and other tissues concerned with protein synthesis. Enlargement of liver with marked pallor and cellular changes were observed after death in some of the cases.

All the eighteen patients had definite hypochromic anaemia, hypoproteinaemia, reduced blood cholesterol and rise in chloride content of the oedema fluid—conditions found in animal experimental starvation oedema. H H S

TROLLE (G.) Syndrome oedémateux cutané et dyschromique. Note préliminaire d'après les médecins du Forearm. [Oedema and Depigmentation of the Skin and Cutaneous Structures.]—pp 37-57 With 1 fig 1938. Brussels Fonds Reine Elisabeth pour l'Assistance Médicale aux Indigènes du Congo Belge 112 rue du Commerce

The syndrome described in this article goes by the local names of Mbwagi kikuba, and kibengi (from bengi—to grow white) or by the French doctors, cheveux blancs. The established disease is characterized by oedema of the integument causing a waxy appearance by severe anaemia, loss of pigment in the hair weakness, articular pains bleeding from the gums and, in some cases, enlargement of the spleen. Children are mostly attacked of 1450 cases 1085 (75.5 per

cent) were children 211 were adult female and 44 men many of the children were still being breast fed.

The following is a more detailed account of the symptoms and course of the disease the onset is gradual with loss of appetite this is followed by marked weakness pallor of skin and hair the skin becoming lemon yellow dry and scaly haemic murmurs develop with foetal cardiac rhythm the liver enlarges red cells 3 000 000 or so haemoglobin 60-70 per cent white cells 6 000-8 000 with relative lymphocytosis and an Arneth index deviated to the right no marked eosinophilia recession of the gums with alveolar periostitis in the later stages cardiac signs increase the abdomen enlarges and the face is swollen and puffy and the hair becomes less and less pigmented. The fatality rate is in the neighbourhood of 15 per cent Some are infested with hookworms but the general opinion is that the cause is a vitamin deficiency in particular vitamin C Treatment is mainly based on these lines—clearing up the ankylostomiasis if present giving a generous diet rich in vitamins and cardiac and general tonics

H H S

AN DALE (G) Sur une affection de carence et de déséquilibre diététique observée au Congo (Buaki des indigènes) [Buaki, a Deficiency Disease in the Congo]—*Ann Soc Bde de Méd Trop* 1938 Dec. 31 Vol. 18. No 4 pp 653-669

Among the inhabitants of many villages in certain parts of Kwango (Congo) some proportion may be immediately picked out as suffering from an affection giving rise to a very characteristic appearance a dull dry rough scaly or nutmeg grater like skin with general loss of pigment of varying degree desquamation of the skin of the palms and soles the hair thinned lank and depigmented with perhaps patches of alopecia loss of weight and muscular wasting sometimes cachexia the face puffy the lower extremities oedematous as also the genitalia a distended abdomen with moderate ascites and sometimes mild diarrhoea perianthicular rheumatic pains and marked anaemia complete the picture On the other hand there are no signs referable to the nervous system or special senses no visceral or bony lesions no other gastro-intestinal symptoms no stomatitis no albuminuria. The affection is recognized by the natives and called Buaki. It affects women and children, chiefly the forsaken wife or the orphan very rarely a male this incidence at once suggesting that it is a condition due to dietetic deficiency The diet at best consists of manioc with a minimum of maize and ground nuts rarely bananas beans and fruits are hardly known meat is never eaten and the only supplements may be insects small animals roots and a little palm wine. The condition does not respond to an exhibition of vitamins but improves when a well balanced mixed diet is given. It is therefore considered to be due to an unequilibrated diet in which there is an excess of carbohydrate but lack of protein probably in association with vitamin insufficiency

H S S

POUHIN (E) Syndromes d'oedèmes par carence alimentaire dans le cercle de Zagora (Maroc) [Oedema from Diet Deficiency in Zagora (Morocco)]—*Bull Soc Path Exot* 1939 July 12. Vol. 32. No 7 pp 769-779

The author during a residence of 2½ years in the district saw several cases of oedema due to more than one cause. Some seemed to

malarial in origin and cleared up when quinine was given others were due to insufficient food—a famine oedema, others again to debility following typhus, and a fourth class ascribed to imbalance of diet. Only four showed any nervous symptoms, two with polyneuritis of the legs and flaccid paraplegia and two with polyneuritis of one side affecting mainly the extensors. All four recovered, two of them promptly on being given vitamin B₁.

Analysis of the diet of the inhabitants of Draa shows a definite reduction of animal proteins below the amount necessary for adequate nutrition and as for vitamin content—dates were the main source—100 gm yielded 200 units of vitamin A 30 I.U. of B₁ traces only of B₂ and no C or D (sometimes traces of the last). Administration of synthetic vitamin had little effect, the most successful treatment was addition of meat and lemons. H H S

VIDAL (Antonio) Avitaminosis compleja infantil [Mixed Avitaminoses in Children].—V Congreso Médico de Centro América y Panamá 6 pp With 5 figs.

The chief symptoms of the condition described [as occurring in Honduras?] are oedema of the legs, and involving sometimes the arms and face coldness of the extremities with cyanosis, congestion perhaps inflammation of lips and gums—*signo del colorote* (the rouge sign)—and in some a certain degree of stomatitis. An erythema of the legs may extend over the abdomen and nates and even to the arms. It resembles pellagra in being symmetrical and in severe cases desquamation may continue for weeks or even months. As in pellagra too there occur attacks of gastro-intestinal disturbance with diarrhoea in nearly all cases. Bleeding from the gums is sometimes seen, and conjunctivitis and xerosis. The blood shows little change beyond a moderate anaemia and reduction of haemoglobin. The oedema is not due to ankylostomiasis. Those affected are of the poorer classes, living in unsanitary conditions, on a diet consisting largely of maize. There is considerable resemblance to the *calebrilla* of Mexico [see this Bulletin 1937 Vol 34 p 247 and Bull of Hyg 1935 Vol 10 p 806] and kwashiorkor of the Gold Coast [see this Bulletin 1934 Vol 31 p 344 and Bull. of Hyg 1936, Vol 11 p. 311].

The present article records 15 patients, of ages ranging between 15 months and 6 years, but it is said to be most common between two and four years. Sex seems to play no part of these 15 eight were boys and seven were girls. Five died three males and two females. If coming under observation in time they did best on a generous diet of milk eggs green food, tomato-juice and for medicine calcium lactate. H H S

DEBDAZ (Nanigopal) Secondary Purpura in Chronic Diarrhoea in Children due to Hypovitaminosis-C.—*Calcutta Med. J.* 1939 May Vol 35 No. 5 pp 394-396

Three cases are recorded of children who after troublesome diarrhoea over periods of 6 to 12 weeks developed purpuric symptoms. The author ascribes this secondary purpura to two causes first that on account of the diarrhoea the diet was restricted and vitamin C deficient, and, second, that what was ingested was rapidly got rid of in the frequent motions. It is important, therefore in such cases not to keep

too much or too long to starchy foods and to give vitamin C as orange-juice the amount needed of the latter is not sufficient to aggravate the diarrhoea.

MALARIA.

PRÉCIS OF ABSTRACTS IN THIS SECTION

COVELL (p 917) has given a full account of the history of malaria in Delhi.

Two persons reported by TANGUY (p. 917) contracted malaria near Fréjus in the French Riviera

HÉRIVAUX *et al* (p 918) have studied malaria in the New Hebrides. The form is mild but *P. falciparum* is the most common parasite. There is a marked relationship between malaria and rainfall, suggesting seasonal breeding of *A. punctulatus* the only Anopheles found which is found to have very catholic habits. Eradication of this mosquito might be comparatively easy

MISSIROLI (p 919) discusses the nomenclature of *P. falciparum* and GIOVANNOLA (p 919) concludes that *P. tenue* is not a valid species

ROUBAUD (p 919) shows that exceptional individuals of *A. maculipennis labranchiae* usually markedly anthropophilic may show zoophilic tendencies. In Portugal, CAMBOURNAC (p 920) found larvae of *A. maculipennis atroparvus* generally spread throughout ricefields but more numerous when there was growth of the alga *Spirogyra*. There is considerable mortality in each larval instar. WEYER and BOCK (p 920) found a higher mortality in infected than in non infected mosquitoes. *A. maculipennis* transmits *P. vivax* better than *P. falciparum* the latter being best transmitted by *A. superpictus* among the Anopheles used and giving an infective index of 81 per cent. PORTER and HOCKING (p 921) have devised an apparatus for testing the effect of insecticides on flying insects and from which samples of air can be removed for examination.

BOYD *et al* (p 922) showed experimentally in man that current or recent infection with either *P. vivax* or *P. falciparum* in no way interferes with successful infection with the other

The injection of non-specific protein (e.g. milk) is considered by SCHLESINGER (p 922) to cause the coarsening of granulations existing in the blood cells thus rendering them visible. In a proportion of patients with latent malaria this procedure caused typical Schüffner's or Maurer's dots to appear

LENTJES (p 923) reports that in fresh benign tertian infections 0.6 gm hydrochloride of hydroquinone daily for 7 days is superior to quinine. It cuts short the attack promptly inhibits the production of gametes diminishes relapses and has little toxicity. HAVER (p 923) quotes a patient in whose family hypersensitivity to quinine in the form of general urticaria has been present through three generations

CIUCA *et al* (p 924) show that quinine and atabrin even if combined with plasmoquine do not prevent the appearance of gametocytes

but a single dose of 2 cgm. plasmoquine will eliminate existing gametocytes as effectively as large daily doses. It is therefore logical to give this dose 3 or 4 days after completion of a course of schizonticidal drugs and to repeat it at intervals of 5 days.

During atebirin treatment BOCK (p. 924) has noted clumping followed by extrusion of the pigment, solution of the cytoplasm and shrinking and breaking up of the chromatin. The effect is therefore apparently directly on the parasites. KOSTIĆ and ANTIĆ (p. 924) gave 0.4 gm. atebirin each week to a carefully observed group of prisoners and warders in Yugoslavia. This dose was divided between two successive days. The infection rate diminished, there were no ill-effects and all continued at work whereas in the controls the infection rate increased considerably.

SIXTOX *et al.* (p. 925) come to the conclusion that prosectazine appears to have a true causal prophylactic action against the sporozoites or forms between sporozoite and trophozoite, of the strain of *P. falciparum* used in careful experiments on 8 patients.

MACDONALD (p. 926) has designed a cheap effective syphon for the automatic flushing of streams in the control of *A. culicifacies* breeding in Ceylon. In Freetown the investigations of PEASTON and REXNER (p. 926) indicate that an area hyperendemic in 1926 has been converted to a condition of endemicity like that of the rest of the town probably owing to the permanent canalization of a watercourse and drainage into it.

Malaria of monkeys and birds—Using an antigen prepared from the paritized red cells of monkeys dying from *P. knowlesi* infection EATON and COGGESHALL (p. 926) observed strong complement fixation with sera of persons infected with *P. knowlesi*, *P. vivax* or *P. falciparum*. The reaction is therefore group specific. MOSKOW (p. 927) shows that immune bodies are developed in the serum of monkeys with *P. knowlesi* infection, which when injected in large quantities into others at the time of infection modify the disease to a chronic rather than immediately fatal, infection.

RODMAN *et al.* (p. 928) failed to infect man and other monkeys with the parasite of chimpanzees which resembles *P. vivax*. They therefore consider it to be a distinct species. BRUMPT (p. 928) considers that the three plasmodia of chimpanzees which resemble the three common parasites of man, are probably on morphological and pathogenic grounds, distinct from the latter. One is known as *P. reichenowi* and he suggests that the others be named *P. schreineri* and *P. rodhaini*.

RECHAUD *et al.* (p. 928) find that *Aedes gressittii* permits complete development of *P. gallinaceum*.

HEWITT (p. 929) shows that the blood of fowls infected with *P. gallinaceum* by means of mosquitoes is not itself infective for 4 or 5 days.

HEWITT (p. 929) confirms the finding that young *P. cathemerium* parasites enter young red cells only, both reaching maturity at about the same time except during the crises when exceptionally young red cells are present and are attacked.

GAVERILOV *et al.* (p. 929) found that *P. gallinaceum* survived for 10 days in culture of bone marrow but failed to do so in fowl spleen tissue culture.

HECKER and WOLFSON (p. 929) failed to separate erythrocytic and exoerythrocytic schizonts by means of tissue culture of infected brain, lungs and spleen, and inoculation into birds.

GIOVANOLA (p 930) considers the toxoplasma like bodies seen in *P. gallinaceum* infections of fowls to be stages in the development of that parasite and calls attention to two inclusions probably parasitic in the mononuclear blood cells. CHOKTIS (p 930) considers that exoerythrocytic schizonts are forms which develop abnormally after ingestion of young parasites by the reticulo-endothelial cells the latter showing some loss of function. The reticulo-endothelial system shows marked proliferation in *P. gallinaceum* infections. RAFFAELE (p 931) suggests that the exoerythrocytic schizonts of birds may give rise to two kinds of merozoites one for continuance of exoerythrocytic development the other for initiation of erythrocytic development. A similar cycle may occur in man.

Only the exoerythrocytic schizonts in *P. gallinaceum* infection give a definite reaction by Feulgen's method according to UNGO-MUGDAN (p 931).

Mosquito transmission was responsible for an outbreak of *P. relictum* infection in penguins in Antwerp and RODHAIN (p 931) found exoerythrocytic schizonts in these birds and in another infected by inoculation. These schizonts are more resistant to atebrian than the ordinary parasites.

DÉMINA (p 932) studied the natural resistance of birds to *P. relictum*.

MOSEKOVSKY and SYRKINE (p 932) found that certain acridine compounds active against bird malaria cause the appearance of small granules in the red cells of mice and birds.

DURAND and VILLAIN (p 932) failed to influence infection in pigeons with *Haemoproteus columbae* by the use of sulphanilamide derivatives.

COVELL (G) Antimalaria Operations in Delhi. Part I.—*Jl Malaria Inst of India* 1939 Mar Vol. 2, No 1 pp 1-61 With 6 maps (1 folding) 1 chart & 26 figs on 13 plates. [20 refs]

This part of the report contains a detailed account of the history of malaria in Delhi of the nature of the malaria problems in different parts of the Delhi urban area and of the distribution and intensity of malaria infection in Delhi in 1896 when the last antimalaria campaign was started. Clear maps good photographs of different types of anopheline breeding places abundant tables giving weekly climatic data for seven years morbidity data, mortality data and spleen rates recorded by different observers between 1909 and 1896 supplement the letterpress. It is an unusually fully documented report and in consequence does not lend itself to summary in small space.

Norman White

TANGUY (Y) Observation de paludisme contracté en France (Saint Aygulf) (Malaria contracted in France)—*Bull Soc Path Exot* 1939 Mar 8 Vol. 32, No 3 pp 285-296

This is a brief note concerning a patient who acquired a *P. vivax* infection in the south of France. She had never been outside France and never visited any place where malaria is endemic. During three years she passed some of the summer months in Saint Aygulf in a house one and a half kilometres distant from the military camp at

Fréjus in the Riviera. During the last of these visits in 1937 she contracted malaria. Her husband appears to have contracted the disease at the same time. V II

HÉRIVAUX (A.) ROYER (P.) & DAO VAN THAI. Contribution à l'étude du paludisme des Nouvelles-Hébrides. Recherches effectuées à Port Vila et alentours [Malaria in the New Hebrides. Investigations in Port Vila and Neighbourhood.]—*Ann de Méd et de Pharm Colon* 1939 Jan.-Feb.-Mar Vol 37 No 1 pp. 40-62 With 6 graphs.

This report is of special interest because apart from BUXTON'S Report (this Bulletin 1927 Vol. 24 p. 841) on the Islands of the Southern Pacific no precise information has been published about malaria in the New Hebrides. From the malaria point of view the New Hebrides are of special interest because they mark the limit of extension of indigenous malaria in the Pacific to the south and east. In Fiji and New Caledonia, relatively so near to the New Hebrides as distances go in the Pacific, indigenous malaria is unknown.

The years observations recorded were carried out in and around Port Vila in the Island of Vati the chief island of the group. Vati has 2,800 inhabitants half of whom live in Port Vila. There are 1,600 belonging to the indigenous Melanesian race, 500 Europeans, French and English, and 700 Asiatics. Not all are of pure descent. There are numerous half-castes especially among the French population. The authors refer to the mixture of blood as a 'cocktail of blood'.

In the French Hospital at Port Vila of 3,102 patients treated during 1937 (both in-patients and out-patients) 604 were suffering from malaria. The disease occurs in mild form and is hardly ever fatal, even among infants. It is very amenable to treatment. Pernicious attacks are very rare. There were two in 1937 both among natives. Haemoglobinuric cases occur from time to time chiefly among Asiatics, but even these cases are rarely fatal.

Parasites were found in 307 cases during the year. *P. falciparum* was found in 242, malar in 61 both in 4. *P. malariae* was never seen. Of 129 school-children aged 5 to 12 examined, 47 had palpable spleens, a spleen rate of 36.4 (not 42.7 as printed in error). The spleen index of 158 members of the labour force community of Tonking origin, in the neighbourhood of Port Vila was 69.23 per cent.

The study of indigenous malaria is complicated by the arrival three or four times a year of batches of labourers from Tonking for work on the French plantations. After a short period of observation at Port Vila these workers are distributed throughout the islands, a considerable number each time remaining in Vati. Numerous attacks of acute malaria are commonly observed among them for a month or two after their arrival unless they happen to arrive in the cool season.

Indigenous malaria of local origin is almost non-existent during the three cool months. July to September rises with the advent of the hot weather and is at its worst towards the close of the hot season when daily variations in temperature are most marked, generally in the month of May. There appears to be a marked relationship between the incidence of malaria and rainfall, a fact which would indicate that the most important anopheline breeding places are temporary and seasonal. This conclusion was confirmed by the observations made.

The only Anopheline was identified by Buxton 14 years ago *A. punctulatus*. No other has been found. The author's observations indicate a marked catholicity in its breeding habits. Larvae have been found in shade and in full sunshine in stagnant and in running water in clear and in muddy waters in large marshes and in small puddles in small artificial collections of water in fresh and in very saline water. It is a domestic mosquito profiting by household negligence. Adults do not appear to fly far. Its eradication might be neither difficult nor costly. A II

MISSIROLI (A.) *Plasmodium immaculatum* Grassi e Feletti (1892) Schaudinn (1902) nome corretto del parassita della terzana maligna. [*P. immaculatum* Correct Name of the Parasite of Malignant Tertian Malaria.]—*Riv di Parassit* Rome 1933 Dec. Vol. 2. No 4 pp 269-273 English summary (6 lines)

In this paper the author reviews the early papers of Grassi and FELETTI dealing with the parasites of human and avian malaria. He concludes that the correct name for the parasite of avian malaria is *Plasmodium praecox* Grassi and Feletti 1890 *P. relicti* being a synonym while that of the human parasite is *Plasmodium immaculatum* Grassi and Feletti 1892 with *P. falciparum* as a synonym [see also this *Bulletin* 1939 Vol. 36 p 390] C M Henyon

GIOVANNOLA (Arnaldo) Ceppi tropicali e ceppi europei di *Plasmodium immaculatum* [Tropical and European Strains of *P. immaculatum*]—*Riv di Parassit* Rome 1933 Dec Vol. 2. No 4 pp 239-304 With 5 figs. 1 graph & 1 plate [23 refs] English summary

Comparing a strain of malignant tertian malarial parasite of Ethiopian origin with one from the Roman Campagna during maintenance in general paralytics the author has observed that in infections due to the tropical strain fully developed schizonts and young crescents occur commonly in the peripheral blood in cases which cannot be regarded as grave. Other features of the tropical parasites are a paucity of pigment the presence of fair-sized rings in the blood and a marked susceptibility to quinine. Differences were also noted in the crescents, due largely to the appearance of the young crescents in the blood in the case of the tropical strain. It is concluded that *Plasmodium tenue* is not a valid species while the tropical strain should be known as *Plasmodium immaculatum* var *perniciosum* (Ziemann 1915) [See MISSIROLI above.] C M H

ROUBAUD (E) Le comportement anthropophile de l'*Anopheles maculipennis labranchiae* étudié dans les conditions expérimentales en insectarium. [Anthropophilic Behaviour of *A. maculipennis labranchiae* under Experimental Conditions in Insectarium]—*Bull Soc Path Exot* 1939 Mar 8 Vol. 32. No 3 pp 295-297

Observations hitherto unpublished, carried out six years ago on a strain of *A. maculipennis labranchiae* obtained from the south of Spain showed the persistence with which this paucidentate species retains its anthropophilic feeding habits to the third generation bred in captivity. Experiments carried out in small cages 1/20 cubic metre revealed the fact, however that in any given lot bred together certain individuals

LOYD (Mark F) KITCHEN (S F) & MATTHEWS (Chace B)
Consecutive Inoculations with *Plasmodium vivax* and *Plasmodium*
falciparum — *Amer J Trop Med* 1939 Mar Vol. 19 No. 2
pp. 141-150

Four patients inoculated with *P. vivax* were subsequently inoculated with *P. falciparum* and four inoculated with *P. falciparum* were subsequently inoculated with *P. vivax*. In two patients of each group the subsequent inoculation was made during the incubation period of the parasite first injected in one of each during a clinically active attack and in one of each following a recent attack. The results show that current or recent infection with either *P. vivax* or *P. falciparum* in no way interferes with successful infection with the other. Superinfection with the heterologous species during the incubation period gave one positive and one negative result in each group. The negative results could not be attributed to immunity of the test subjects nor are they likely to have been caused by an antagonism between the two species. The observations demonstrate the absence of cross immunity between *vivax* and *falciparum* infections. \ II

SCHLESINGER (Annemarie) Ueber Beeinflussung der Blutzellgranulationen durch Milchinjektion. The Influence of Milk Injection on the Granulations in Blood Cells. — *Folia Haematologica* 1939 Vol. 62 No. 1 pp. 137-139

The report deals with the examination of the blood of 40 patients before and after intramuscular injection of 5-10 cc of milk. This injection method is employed in Albania by the author as a provocative in cases of latent malaria with negative blood examinations. Positive results are obtained in 10-15 per cent of cases so treated.

In a number of cases studied, a few hours or longer after injection, red cells present in the circulation showed characteristic Schüffner's or Maurer's dots. In a few of these cases such stippling was definitely associated with latent *P. vivax* or *P. falciparum* infections respectively as verified by later finding the parasites. Most latent cases, however as diagnosed by symptoms and history showed only stippling in absence of parasites following injection of milk.

Other cases with fever of unknown origin classified as septic or toxic showed normal erythrocytes but had a characteristic granulation in 20-35 per cent of mature neutrophil white cells as a result of injection. The author considers that the parenteral administration of non-specific protein causes the granulations previously present but not detectable to be coarsened and rendered visible. The staining method employed was carefully controlled. J. D. Fulton

LE BURDELLÈS (B) La sérologie du paludisme. Ses techniques actuelles. Ses applications. Ses résultats. [Serology of Malaria. Technique, Application, and Results. — *Rev. Service Santé Milit.* 1939 Feb Vol. 110 No. 2 pp. 267-297 [10 refs]

A clearly written dissertation on malaria flocculation which takes account of most of the recently published work. It contains no new observations.

LE TIES (L J N) Malariabehandeling met het alkaloid hydrochinine [Malaria Treatment with the Alkaloid Hydroquinine]—*Geneesk Tijdschr v Nederl Indië* 1939 May 2 Vol 79 No 18 pp 1090-1101

Hydroquinine a reduced quinine with two hydrogen atoms more than quinine has been neglected in the treatment of malaria although original reports have been uniformly favourable to its use. In the present series of 262 patients suffering from fresh infections and not relapses treatment consisted in a daily 3 portion dose of 0.6 gm. hydrochloride of hydroquinine continued for exactly 7 days. The blood of all the patients was examined daily and was not pronounced negative until it was found to be free of schizonts in thick drop on 3 successive days. Freedom from fever meant that the patient's temperature did not rise above 37°C (98.6 F). Out of a series of 200 benign tertian cases this freedom from fever was attained after the 1st 2nd, 3rd 4th and 5th day by 80 81 35 3 1 patients respectively. 'The influence of the drug on the schizonts was no less satisfactory. Out of 217 patients suffering from tertian malaria 41 74 63 27 6 and 1 were free of schizonts after the 1st 2nd 3rd 4th 5th and 6th days of treatment respectively. Other satisfactory features of the use of hydroquinine instead of quinine were the tolerance of the drug the absence of such complications as deafness tinnitus dizziness nausea vomiting and diarrhoea. It would seem therefore according to the summary that hydroquinine has a prompt effect on the malaria attack an inhibiting action on the production of gametes is capable of diminishing relapses, acts in small doses is readily eliminated possesses little toxicity and is generally superior to quinine.

W F Harvey

HAUER (A) Beispiel einer familiären Form von vererbbarer Chinin-unterempfindlichkeit [Example of a Familial Form of Inherited Quinine Hypersensitivity]—*Arch. f. Schiffs u Trop Hyg* 1939 May Vol. 43 No 5 pp 203-205 With 1 fig

The author had under his care a female aged 51 from Peru suffering from an old duodenal ulcer. She had an intercurrent attack of influenza and she requested that quinine should not be administered as she was highly sensitive to it. She informed him that about half an hour after a dose of quinine severe symptoms developed viz continuous coughing feeling of choking and unbearable itching accompanied by urticaria involving the whole of the skin of the body. The author investigated the family history of the patient and obtained the following information. Apparently the hypersensitivity commenced in the patient's father who lived in Peru and took small doses of quinine in the form of bark. He handed on the abnormality to the patient and her sister the daughter of the former also suffered from hypersensitivity to quinine. The abnormality had thus been passed on through the female members of the family to the third generation. In later generations the author considers that the symptoms of hypersensitivity will increase in severity. He is of opinion that as quinine is very largely used in the treatment of such cosmopolitan diseases as influenza, pneumonia etc. it is important that not only should the patient inform the doctor regarding the hypersensitivity but that there should also be a medical record to accompany the patient.

- CICCA (M.) BALLIF (L.) CHELARESCO (M.) & LAURINENCO (N.)
Contributions à l'étude du *Pl. falciparum* (Observations sur une souche de parasite qui a subi de nombreux passages) [Observations on a Strain of *P. falciparum* which has undergone Numerous Passages].—*Arch. Roumaines Path. Expér. et Microbiol.* Paris. 1938. Mar. Vol. 11. No. 1. pp. 85-101. With 9 graphs.

During the course of malarial therapy of general paralysis in Rumania 154 passages of a strain of *Plasmodium falciparum* were made on 1,071 patients. The majority of these were by direct blood inoculation but a number were mosquito transmissions. During all these passages no change in the morphology or virulence of the parasite was noted. In a series of tables the data relating to these infections are given—incubation periods, time of appearance of trophozoites and gametocytes, effect of treatment by quinine, atabrin or plasmoquine, the rapidity of development in mosquitoes and so on.

It is shown that in general drugs act more slowly on cases which had been infected by mosquitoes than by blood inoculations. The schizonticidal drugs, quinine and atabrin, whether combined with plasmoquine or not, did not prevent the appearance of gametocytes in a series of 149 out of 269 cases. On the other hand a single dose of plasmoquine (2 cgm.) was just as effective in getting rid of gametocytes in 53 cases as was the administration of large daily doses of this drug during the course of administration of quinine or atabrin during the attack in 110 cases. The results indicate that it is logical to administer a dose of plasmoquine (2 cgm.) three to four days after the completion of a course of schizonticidal drugs (quinine or atabrin) and to repeat this dose at five-day intervals. C. V. NEWSON

- BOCK (Erich). Ueber morphologische Veränderungen menschlicher Malariaparasiten durch Atebrinwirkung. Morphological Changes in the Human Malaria Parasites due to Atebrin.—*Arch. f. Schiffs- u. Trop. Hyg.* 1939. May. Vol. 43. No. 5. pp. 209-214. With 7 figs. [11 refs.]

In a study of the changes undergone by the parasites of human malaria, including *Plasmodium ovale* during atabrin treatment the author has noted, as others have already done, that the first is the clumping followed by extrusion of the pigment. This change may be observed especially after intramuscular injection of the drug within a few hours of the commencement of treatment. Further changes are the solution of the cytoplasm and the shrinking of the chromatin which finally breaks into several separate clumps. As all the parasites react in much the same manner it would seem that the drug is one which acts directly on the parasites. C. V. NEWSON

- KOSTIĆ (Dušan) & ARNČIĆ (Dušan). Zur Malaria Prophylaxe mit Atebrin (Malaria Prophylaxis with Atebrin).—*Arch. f. Schiffs- u. Trop. Hyg.* 1939. July. Vol. 43. No. 7. pp. 306-311. With 1 fig.

The authors carried out prophylactic experiments with atabrin in a region of endemic malaria in Jugoslavia on 240 prisoners and waifs kept under strict surveillance. The observations were made over the whole malaria season, May till October '38, untreated persons acted as controls, and the area of all malarious persons was noted.

A. maculipennis is the chief anopheline of the region but *A. bifurcatus* and *A. superpictus* are also found. The drug was given in 0.4 gram doses per week half of the total being administered on two successive days. Blood examinations were made regularly. During treatment 9 cases were found infected with *P. falciparum* and 5 with *P. vivax*. At the start of the experiment the percentage showing parasites in the blood was 7.5 per cent and at the end fell to 0.8 per cent. in treated cases. Amongst the controls the percentage of infected cases was fairly constant and rose to 46.7 per cent in August. There were no ill-effects from the use of the drug and all treated cases were able to continue at work.

SINTON (J A) HUTTON (E L) & SHUTE (P G) Some Successful Trials of Proseptasine as a True Causal Prophylactic against Infection with *Plasmodium falciparum*—*Ann Trop Med & Parasit* 1939 Mar 31 Vol 33 No 1 pp 37-44 [19 refs]

The observations described were carried out on eight patients requiring malaria therapy. Proseptasine is a benzyl derivative of alphanilamide para benzylaminobenzenesulphonamide. In order to ascertain whether such malaria prophylactic properties as this drug might possess were really causal that is operative against sporozoites and intermediate forms between sporozoites and trophozoites the administration of the drug was in no case continued later than the day following the application of infected mosquitoes to the patient. A Rumanian strain of *P. falciparum* was employed. From 15 to 20 heavily infected *A. maculipennis* var *atroparvus* applied to each patient assured that each received a larger dose of infection than would commonly be acquired in nature.

Three patients each received 7.5 gm. proseptasine during the 24 hours before the infecting bites and a further 4.5 gm. during the subsequent 8 hours. The discovery of a single parasite in the blood of one of these patients on the 12th day after the bites was the sole evidence of malaria infection in this group. An untreated control patient developed an acute attack of malaria after an incubation period of 11 days.

Two patients received 12 gm. of the drug during the 24 hours before the infecting bites and an additional 15 gm. during the subsequent 32 hours. One of these patients developed fever and parasites 22 days after the infecting bites.

Three patients received 3 gm. of the drug three times at four hourly intervals. One was bitten by infected mosquitoes immediately after the last dose the second 24 hours later the third 48 hours after the last dose. The first and the last of these patients developed acute attacks of malaria after incubation periods of 15 and 16 days respectively.

Thus of the 8 patients 5 showed no clinical or parasitological signs of infection though they had been under close observation from 4 to 5 months. Proseptasine appears to have a true causal prophylactic action against the strain of *P. falciparum* used. In view of the precautions necessary during treatment with sulphonamide compounds and the short duration of the prophylactic action observed, the observations have very limited practical applicability.

CLARK (Herbert C.) Review of Recent Research on Drug Prophylaxis and Treatment of Malaria.—*Southern Med J* 1939 July Vol. 32 No 7 pp 685-689 [30 refs.]

MACDONALD (G.) A Design of Flushing Siphon for Control of Anopheline Breeding.—*Jl Malaria Inst of India*. 1939 Mar Vol. 2 No 1 pp 63-69 With 1 text fig & 13 figs. on 4 plates.

Inspired by the work of WILLIAMSON and SCHARFF the author has evolved a siphon for the automatic flushing of streams which has been used with success in Ceylon in the control of *A. culicifacies* breeding. Detailed scale drawings of its construction are reproduced. It is made in three parts, core, case and cover they are each cast in concrete 2 inches thick reinforced with $\frac{1}{2}$ inch steel rods. It is standardized and made in a central depot. It gives an automatic discharge of 475 gallons of water a minute. It can be used singly or in parallel with others. Only a low dam is required for successful operation about 29 inches. It withstands rough treatment and is retailed at a cost of Rs 25 (37s 6d). The heaviest part of the siphon can be carried over rough country by four labourers. It is simple and ingenious and should have a wide field of application. N IV

PEASTON (H.) & REKKER (E. A.) Report on an Examination of the Spleen and Parasite-Rates in School-Children in Freetown, Sierra Leone.—*Ann Trop Med & Parasit* 1939 Mar 31 Vol. 33 No 1 pp 49-62. With 1 map & 4 figs. on 2 plates. [10 refs.]

The results of the examination of 951 children in schools in Freetown, aged from 3 to 10 years, are recorded in this paper. The observations were made in November and December 1935 the most malarious season. The findings are compared with those of previous surveys, notably that of MACDONALD in 1928. Macdonald had found malaria to be hyperendemic in the western half of the town and endemic in the remainder. The spleen rate of the 951 children was 43 per cent. 44.1 for the endemic area and 42.6 for what had been the hyperendemic area. The corresponding parasite rates were 36.3 34.0 and 38.5 per cent respectively. This indicates that the hyperendemic area no longer exists and that malaria is almost equally endemic throughout the city. This improvement is ascribed to the permanent canalization of Sander's Brook and the permanent drainage of the streets draining into that water course. A brief account is given of that work.

The examination of blood films showed a remarkable predominance of *P. malariae*. Of the 345 positive blood films 167 contained *P. malariae* 133 *P. falciparum* 40 both *P. malariae* and *P. falciparum* 4 *P. vivax* and 1 *P. malariae* and *P. vivax*. N IV

EATON (Montee D.) & COGGESHALL (L. T.) Complement Fixation in Human Malaria with an Antigen prepared from the Monkey Parasite *Plasmodium knowlesi*.—*Jl Experim Med* 1939 Mar 1 Vol. 69 No 3, pp. 379-393 With 4 figs. [14 refs.]

The authors have previously reported the development of specific complement fixing antibodies in monkeys infected with *P. knowlesi*.

[see this *Bulletin* 1939 Vol 36 p 404] In this paper observations are described on the sera of normal human beings patients with syphilis patients undergoing malaria therapy with either *P knowlesi*, *P vivax* or *P falciparum* and of patients suffering from naturally acquired malaria. Four *knowlesi* antigens were used prepared either from the blood or from the spleen of monkeys dying from *knowlesi* infections. The parasitized red cells were concentrated frozen dried and preserved in sealed tubes. The spleens were dried in a similar manner.

Antigen 1—Dried red cells were rehydrated 10 cc. of saline being added to the equivalent of 1 cc. of packed cells. The suspension was frozen and thawed 4 times and then centrifuged. The supernatant fluid was the antigen. It was not anticomplementary and was used in tests in a dilution 1 : 4.

Antigen 2—Dried parasitized cells were ground in a ball mill and extracted with saline dilution as in 1. This antigen was slightly anticomplementary and was used in tests in a dilution 1 : 10.

Antigen 3—Prepared from dried spleen by method similar to that used in the preparation of Antigen 2, 1 gm. of dried spleen to 10 cc. of saline. It was definitely anticomplementary and was used in tests in a dilution of 1 : 10.

Antigen 4—Dried spleen was rehydrated 1 gm. dried spleen to 10 cc. saline frozen and thawed as in the preparation of Antigen 1. This antigen was anticomplementary in a dilution of 1 : 2. It was used in tests in a dilution 1 : 12.

Antigen N was prepared from normal monkey red cells with technique similar to that used in the preparation of Antigen 1.

In carrying out the tests the technique used was the same as that used for monkey sera described in a previous paper except that 2 units of complement were used in place of 2½.

The malarial antigens gave negative complement fixation reactions with from 70 to 80 per cent. of luetic and normal sera and weak or doubtful reactions with the remainder. Some human sera gave weak positive complement fixation reactions with antigen prepared from normal monkey red cells the percentage being slightly higher with malarial sera than with normal or luetic sera.

The most specific and sensitive antigen was Antigen 1. It gave strong complement fixation with sera of persons infected with either *P knowlesi*, *P vivax* or *P falciparum*. The reaction is thus group-specific rather than species-specific.

Absorption of malarial human sera with normal monkey red cells does not remove the immune bodies which fix complement with malarial antigens. N IV

MOSNA (Ezio) Contributo allo studio dell'immunità nell'infezione malarica. [Immunity in Malarial Infection.]—*Riv di Parassit* Rome, 1938 Dec. Vol. 2, No. 4 pp. 327-337 [14 refs.] English summary (10 lines)

The author has shown that the serum of monkeys suffering from chronic *Plasmodium knowlesi* infections contains immune bodies of a protective nature. If such serum is injected in large quantities into monkeys at the time of inoculation with this parasite the course of the infection is modified to the extent that it becomes chronic instead of being immediately fatal. The substances are present in the serum in small amount only.

RODHAIN (J) with the collaboration of L. VAN HOOFF & G. MUYLLE.
Contribution à l'étude des plasmodium des singes africains. Les
plasmodium des chimpanzés du Congo Belge [Plasmodia of
Chimpanzees of the Belgian Congo]—*Ann Soc Belge de Méd*
Trop 1938 June 30 Vol. 18. No 2. pp. 237-253 With 2 charts.

The author observed in chimpanzees imported to Antwerp from the Belgian Congo malarial parasites of the types which resembled *Plasmodium falciparum* and *P. vivax*. Both these forms the author shows to be easily inoculable to uninfected chimpanzees but not to other monkeys or human beings. Previous failures to inoculate the former of these parasites to man led to the name *P. reichenowi* being given to it. Though in one case MESNIL and ROUBAUD were successful in producing a transitory infection of human *P. vivax* in a chimpanzee the failure to infect man with the chimpanzee *P. vivax*-like parasite rather suggests that it also may be a species distinct from that of man.

C M IV

BRUMPT (E) Les parasites du paludisme des chimpanzés. [The Malaria Parasites of the Chimpanzees.]—*C R Soc Biol* 1939 Vol 130 No 9 pp 837-840

It is well known that the chimpanzee is liable to infection with malarial parasites which resemble the three well-known forms of man. This resemblance is so marked that REICHENOW and others who followed him regarded them as identical. Nevertheless the form with crescentic gametocytes was later given the name *Plasmodium reichenowi*. Recent work by RODHAIN and his co-workers has shown that while two of these chimpanzee parasites are easily inoculable to other chimpanzees they are non-infective to man and fail to infect *Anopheles maculipennis* [this *Bulletin* 1938 Vol 35 p 816]. It would appear therefore that *P. reichenowi* and the *P. vivax*-like forms are different from the corresponding human parasites. It is probable that the *P. malariae*-like form would also be found to be non-inoculable to man. Furthermore the author of the present paper notes that there are actually certain morphological differences between the human and chimpanzee parasites. Accordingly he suggests that the *P. vivax*-like parasite of the chimpanzee be named *P. schweileri* and the *P. malariae*-like form *P. rodhaini*; the *P. falciparum*-like parasite already having been named *P. reichenowi*.

ROUBAUD (E.) COLAS-BELCOUR (J) & MATHIS (M) Transmission de *Plasmodium gallinaceum* par *Aedes geniculatus* [Transmission of *P. gallinaceum* by *Aedes geniculatus*]—*Bull Soc Path Exot* 1939 Jan 11 Vol. 32. No. 1 pp 28-30

It has already been shown by BRUMPT that the malarial parasite of fowls *P. gallinaceum* develops completely in two species of *Aedes* viz. *A. aegypti* and *A. albopictus* both of tropical origin. The authors of the present paper show that complete development will occur also in *Aedes geniculatus* a tree-hole breeder of France.

HENRY (Ch.) Pouvoir infectant du sang au cours de l'incubation du paludisme de la poule (*P. gallinaceum*) inoculé par moustiques [Infectivity of Blood during Incubation of Fowl Malaria]—*Bull Soc. Path. Exot* 1939 Jan 11 Vol. 32, No 1 pp 30-34

After feeding mosquitoes infected with *P. gallinaceum* on two fowls blood of these fowls was taken daily and injected into others. It was found that not till after the fourth or fifth day was the blood infective. This demonstrates that after mosquito infection there follows a latent period of four or five days before parasites are present in the blood. It is not till two days later that parasites can be detected microscopically. In discussion following the reading of this paper DECOURT states that he has noted a similar latent period following the intraperitoneal inoculation of infected blood. C M W

HEWITT (Redginal) Numerical Relations between Young Red Cells and Parasites throughout the Patent Period in Infections with *Plasmodium cathemerium*—*Amer J Hyg* 1939 Mar Vol 29 No 2, Sect. C, pp 45-59 With 2 figs [21 refs]

Working with *Plasmodium cathemerium* infections in canaries the author has been able to confirm the work of HEGNER and ESKRIDGE (this Bulletin 1939 Vol. 36 p 338) showing that a definite relationship exists between the parasites of different ages and the red cells of different types. This relationship remains fairly constant during the time that parasites are present in the blood. It means that the young malarial parasites enter young red cells only and that both achieve maturity at approximately the same time. At the time of the crises however there appear in the blood red cells which are exceptionally young and when these are attacked by the young parasites the latter attain maturity before the red cells are mature. C M W

GAVRILOV (W) BOBKOFF (G) & LAURENCIN (S) Essai de culture en tissu de *Plasmodium gallinaceum* (Brumpt) [Attempt at Tissue Culture of *Plasmodium gallinaceum*]—*Ann Soc. Belge de Méd. Trop* 1938, Sept 30 Vol 18 No 3 pp 429-434

The malarial parasite of the fowl *Plasmodium gallinaceum* will remain alive and retain its virulence for 21 days in defibrinated blood kept at a temperature of 0-5°C. Under the same conditions parasites in heparinized blood were alive and infective after 10 days but not after three weeks. In spleen tissue culture of adult or embryo fowls the parasites did not survive though they did so for 10 days in cultures of the marrow. It was determined by inoculation of infected blood into the allantoic vessels of the chick embryo at the eighth day of development that the embryo of this age is not susceptible to infection. C M W

HEGNER (Robert) & WOLFSON (Fruma) Tissue-Culture Studies of Parasites in Reticulo-Endothelial Cells in Birds infected with *Plasmodium*.—*Amer J Hyg* 1939 Mar Vol 29 No 2, Sect. C, pp. 83-87

With a view of separating if possible the red cell inhabiting forms of *Plasmodium cathemerium* from the exoerythrocytic schizonts

tissue cultures of the brain lungs and spleen of infected birds were made. After eight days of culture the tissues were inoculated to healthy birds. These became infected with malarial parasites and showed also exoerythrocytic schizonts. It is held that the experiments were inconclusive as even fifteen days after the cultures were made exoerythrocytic schizonts could still be detected in the macrophages though after this interval the cultures did not produce infections.

GIOVANTOLA (Arnaldo) *Il Plasmodium gallinaceum* Brumpt i corpi toxoplasma-simili ed alcune inclusioni di probabile natura parassitaria nei globuli bianchi del *Gallus gallus*. [*P. gallinaceum* Toxoplasma-like Bodies and Certain Leucocyte Inclusions in Fowls. — *Rendiconti Istituto di Sanità Pubblica* Rome, 1938. Vol. 1 Pt. 2 pp. 518-531. With 2 graphs & 3 plates (1 coloured) 34 refs.]

Studying *Plasmodium gallinaceum* in fowls the author has found that the cycle of development occupies 36 hours. He has also come to the conclusion that the toxoplasma-like bodies or the "exoerythrocytic schizonts" are actually stages in the development of the malarial parasite and not developmental stages of an independent toxoplasma. Attention is called to two kinds of inclusions probably parasitic in nature which may occur within mononuclear cells in the blood of fowls. The first resemble young stages of the malarial parasite and appear to possess one to four chromatin masses. They are rounded and stain faintly. The second have the form of deeply staining granules, rods, rings or commas and in shape resemble organisms of the *Grahamella* or *Eperythrozoon* type. C M IV

CHORTIS (Panagiotis) Su alcuni studi di sviluppo del *Plasmodium gallinaceum* Brumpt. Nota I. [Development of *P. gallinaceum*.] — *Rendiconti Istituto di Sanità Pubblica* Rome, 1938. Vol. 1 Pt. 2 pp. 532-539.

A study of the development of *Plasmodium gallinaceum* in fowls has led the author to the conclusion that the exoerythrocytic schizonts play no real part in the cycle of the parasite but are accidental and due to the phagocytic properties of the reticulo-endothelial cells, which engulf but do not destroy the young parasites. These develop abnormally and become the exoerythrocytic schizonts. C M IV

CHORTIS (Panagiotis) Sulle alterazioni del sistema reticolo endoteliale nelle infezioni da *Plasmodium gallinaceum*. [Alterations in the Reticulo-Endothelial System in *P. gallinaceum* Infections.] — *Riv. di Parasiti*, Rome, 1938. Dec. Vol. 2. No. 4 pp. 315-322. With 4 text figs. & 3 coloured figs. on 1 plate. English summary (6 lines).

In malaria in fowls due to *P. gallinaceum* acute infections are characterized by a marked proliferation of the reticulo-endothelial system. Such infections may lead to profound fatal anaemia due to destruction of red cells or may become chronic with a lower degree of anaemia. If the acute infection is treated early with quinine the reticulo-endothelial response is less marked, while an anaemia of the

aplastic type is present. Exoerythrocytic schizonts are not to be regarded as normal developmental stages of the parasite. They indicate actually a loss of function of the reticulo-endothelial cells which fail to destroy completely phagocytosed parasites. C M W

RAFFAELE (G) La fase primaria dell'evoluzione monogonica dei parassiti malarici. [Primary Phase of the Monogony Cycle of Malarial Parasites.]—*Riv di Malarologia* Sez. I 1938 Vol. 17 No 5 pp 331-343 With 1 fig [11 refs.] English summary.

Discussing the exoerythrocytic stages of bird malarial parasites the author concludes that these forms are developed either directly from sporozoites or indirectly through the products of division of these forms again infecting cells other than red cells. When the exoerythrocytic schizonts are found in birds which have been inoculated with infected blood it is not the erythrocytic forms which have produced them but the products of a previous exoerythrocytic schizogony which are present in the inoculated blood. This supposes that an exoerythrocytic schizont may give rise to two kinds of merozoites: the one (histotropic merozoites) for continuance of the exoerythrocytic development; the other (haematropic merozoite) for the initiation of the erythrocytic development. It is further supposed that the number of haematropic merozoites produced by exoerythrocytic schizogony increases with each such schizogony, but that at any time the number of exoerythrocytic schizonts to be found is dependent on the number of histotropic merozoites produced at a previous schizogony. In favour of the occurrence of a similar cycle in human malaria the author mentions certain suggestive findings of his own in bone marrow of cases infected by sporozoite inoculation. The fact that atebium fails to destroy the non-pigmented forms while it is active against the red cell forms in birds may have its counterpart in the failure of the drug to act as a prophylactic in human malaria. C M W

UNGO-MUGDAA (Armida) La reazione nucleare di Feulgen negli stadi exo-eritrocitici del *P. gallinaceum* Brumpt (1935) [The Feulgen Reaction in the Exoerythrocytic Stages of *P. gallinaceum*]—*Riv di Parassit.* Rome, 1938, Dec. Vol. 2, No 4 pp 323-328 With 2 coloured figs. English summary, (5 lines)

The author has attempted to stain the various stages of development of *Plasmodium gallinaceum* by Feulgen's method and has found that the exoerythrocytic schizonts alone gave a definite reaction.

C M W

RODHAIN (J) L'infection à *Plasmodium relictum* chez les pingouins. [*P. relictum* Infection in Penguins.]—*Ann. Parasit. Humaine et Comparée* 1939 Mar 1 Vol. 17 No 2, pp 139-157 With 2 plates. [16 refs.]

The author describes an outbreak of malaria in a number of penguins in the Antwerp Zoological Gardens. The parasite which corresponded morphologically to known strains of *Plasmodium relictum* was readily

inoculable to canaries and from them after a number of passages back again to a penguin. A feature of the infection in the penguins was the presence in the brain and organs of large numbers of exoerythrocytic schizonts which did not occur in the canaries. The outbreak was undoubtedly due to mosquito transmission and it might have been supposed that the exoerythrocytic schizonts occurred only after sporozoite injection were it not for their occurrence also in the penguin inoculated from the canary. Of two penguins treated with atabrin one recovered. In the one that died parasites no longer occurred in the red blood corpuscles though exoerythrocytic schizonts were present in the organs. It would seem that these forms are more resistant to the drug than the ordinary blood stages. C M W

DÉMIAN (P A) Contribution à l'immunologie du paludisme aviaire. [Immunology of Bird Malaria].—*Med Parasit & Parasitic Dis.* Moscow 1938. Vol. 7 No 4 [In Russian pp. 550-578. With 1 chart. French summary pp. 578-579.]

Working with 8 species of birds the author has shown that as regards their susceptibility to *Plasmodium relictum* they fell into three groups, the sparrow being the least susceptible though it was more susceptible to one strain of parasite than to others. It was possible by comparing the behaviour of the three groups to different dosages of parasites or methods of inoculation to arrive at certain results having a bearing on questions of immunity and premunition. C M W

MOSEKOVSKI (Sh D) & SYRKEVE (S A) On Morphological Alterations in Blood Elements under the Influence of Antimalarial Chemotherapeutic Preparations and Related Compounds.—*Med Parasit & Parasitic Dis.* Moscow 1938. Vol. 7 No 3 [In Russian pp. 386-398. With 11 figs. English summary p. 368.]

Testing a number of compounds for antimalarial properties it was found that a number of the acryline series caused the appearance in the polychromatic erythrocytes of mice and birds of certain blue-staining (Giemsa and Pappenheim) granules. These stain intensely with brilliant cresyl blue in supravital staining. It is significant that it is just those compounds which are active against bird malarial parasites which cause the appearance of these small granules up to 3 microns in diameter in the red cells. DURAND (Paul) & VILLAIN Dérivés sulfamidés et paludisme du pigeon [Sulphanilamide Derivatives and Pigeon Malaria].—*Arch Inst Pasteur de Tunis* 1939. Mar. Vol. 28. No 1 pp. 94-95.

The authors have treated a number of pigeons harbouring *Haemoproteus columbae* with the sulphanilamide derivatives rubiazol and septoplax. The drugs were administered intramuscularly but in the doses given failed to influence the infections. C M W

MISCELLANEOUS

NICOLLE (P) & SIMONS (H) Quels services peut on attendre en pathologie exotique de la mesure de la vitesse de sédimentation des hématies? [The Erythrocyte Sedimentation Reaction in Tropical Medicine].—*Bull Soc Path Exot* 1939 Feb 8. Vol. 32. No 2. pp 223-233 [Bibliography]

This reaction is largely used in differential diagnosis and as a measure of prognosis in numerous diseases in Europe. The authors here set out the general findings in tropical conditions. In amoebiasis the sedimentation rate is accelerated in three-quarters of the cases and is especially related to hepatitis. In kala azar acceleration is constant it decreases with treatment though there may be as is not uncommon in chemotherapy a period of exaggeration of acceleration before the return to normal. In malaria acceleration is general though there may be retardation during an acute attack. In relapsing fever the more numerous the relapses the more rapid the sedimentation. There is acceleration in Weil's disease which serves to differentiate it from catarrhal jaundice in which sedimentation is normal. In one case of rat bite fever the reaction was accelerated and in yaws (as in syphilis) it is rapid in the secondary and tertiary stages. In undulant fever as in typhoid the acceleration at first is only slight and this may be a useful point in diagnosis at a stage when serum and skin reactions are not yet positive. Sedimentation is more rapid in the nodular than in the neural forms of leprosy and the author refers to the reaction of Rubino [see this *Bulletin* 1939 Vol 36 p 691].

In trachoma there is acceleration especially in the second stage of the disease and in lymphogranuloma inguinale acceleration is seen more markedly in the genito-rectal than in the glandular form. If pronounced in the latter it should lead to the suspicion of extension of the disease. In yellow fever sedimentation is delayed.

There are conflicting reports in ankylostomiasis but in tapeworm infection sedimentation is slow. In scurvy the reaction is marked. [Since the acceleration in the sedimentation rate is seen in so many diseases its value in diagnosis which has been claimed is more than doubtful.] C W

MYERS (Victor C.) & EDDY (Helen M) The Hemoglobin Content of Human Blood.—*Jl Lab & Clin. Med* 1939 Feb Vol 24 No 5 pp. 502-511 [41 refs.]

The haemoglobin content of finger capillary blood from 111 healthy adult males and 48 healthy adult females in Cleveland was determined by three methods. Firstly Newcomer's acid haematin method was used the apparatus being calibrated against the oxygen capacity method of van Slyke. Secondly the haemoglobin was calculated from the iron content of the blood. For these determinations the samples were digested with sulphuric acid oxidized with hydrogen peroxide and the colour developed on adding a drop of thioglycolic acid and rendering the solution strongly alkaline with ammonium hydroxide compared colorimetrically with that developed in a standard iron solution similarly treated the error from non-haemoglobin iron was neglected and the iron determined was assumed to be 0.335 per cent. of the haemoglobin. The third set of determinations was made by

adding diluted laked blood to a benzidine reagent, followed by hydrogen peroxide and acetic acid, the purple colour developed being compared colorimetrically with that obtained from a standard solution of blood similarly treated [cf this Bulletin 1938, Vol. 35 p 449]. Agreement between the methods was good and the average haemoglobin values were for males 15.8 gm. and for females 13.0 gm. per 100 cc. blood.

Tables are given summarizing values obtained in some 3000 observations by various authors and the conclusion is expressed that normal adults in good nutrition, not residing at excessive altitudes above sea level show essentially the same concentration of haemoglobin in the blood, without difference due to race or geographic location. The only difference is that due to sex, which has long been recognised. In advanced age the values fall slightly whereas at birth the level is very high being 20 to 22 gm. per 100 cc. Following birth it sinks rapidly reaching 10 gm. between the second and third month after which it rises to 12 gm. between the fifth and six months, where it remains during childhood. The authors figure for males agrees with the mean of the other observers given in the tables but the value for females of 13.0 gm. per 100 cc. is definitely lower than the mean of 13.8 gm. obtained from the tables the reason for this difference is not clear.

SCHALM (L.) Ein kleiner Apparat zur Messung des mittleren Durchmesser der roten Blutzellen. [A Small Instrument for the Measurement of the Mean Diameter of the Red Blood Cells].—*Klin. Woch.* 1939, Apr. 1, Vol. 18, No. 13, pp. 470-471. With 2 figs. [10 refs.]

This small halometer designed by the author and Dr. SCHOUTEN and marketed by ZEISS consists of a tube about 2 cm. wide and 6 cm. long. At the eye end is a half-lens which focuses a scale occupying the corresponding half of the opposite end of the tube. Adjacent to the lens is a slot to carry the blood film so that it covers the half of the field unoccupied by the lens. When any convenient but small source of light at least 3 to 4 metres away is observed through the blood film the eye accommodates so that at the same time the scale is sharply defined through the lens. The observer then sees, in the upper half of the field, half the annular diffraction spectrum produced by the blood film. In the lower half of the field he sees the scale which indicates half of a spectrum, corresponding in size to that of a normal blood. The half-rings in the upper and lower fields are adjusted concentrically by aligning the source of light on the centre mark of the scale, and, as the two half-fields are separated only by a line it is possible to judge whether the spectral rings produced by the blood are equal, smaller or larger in diameter than the corresponding rings of the scale representing those of a normal blood, and therefore whether the blood film under examination represents a normal, macrocytic or microcytic blood. On the right side of the scale are a number of vertical lines in relation to which the large yellow ring of the blood spectrum may be observed. Reading from right to left each division represents an increase of 0.5 μ over the mean cell diameter of normal blood. The instrument is designed merely for quick and rough estimations at the bedside and more accurate apparatus is recommended for precise work.

F. Murgatroyd

GREVAL (S D S) CHANDRA (S N) & WOODHEAD (L S F) On M and N in Blood Groups the Technique of Typing the Antifluids, Findings in 300 Indians, and Associated Considerations—*Indian J Med Res* 1939 Apr Vol 26 No 4 pp 1041-1054 With 1 plate

The technique for grouping and typing blood is described in which the suspensions of cells are mixed with the sera on a slide in a moist chamber and the results read macroscopically in 5 to 15 minutes. Type sera were obtained from rabbits injected respectively with OM and ON cells from donors previously typed by means of commercial anti M and anti N fluids. The anti-OM and anti-ON rabbit sera were then absorbed respectively with ON and OM cells so as to obtain residual anti-M and anti-N fluids. Some degree of non-specific absorption of anti-N substance by OM cells occurs but anti M substance does not appear to be absorbed by ON cells. The quality of fluids obtained in different experiments varied but fluids of good potency and specificity were used to test 300 Indians in Calcutta hospitals and the following results were obtained M 42.7 per cent. N 10.7 per cent. and MN 46.7 per cent. A small series of Europeans was typed and a table is given showing the results together with the comparative findings of other workers elsewhere. The forensic application of typing is pointed out. Factors M and N are both dominant and the genotypes of the phenotypes M MN and N are MM MN and NN so that (1) the agglutinogens M and N cannot appear in the blood of a child unless present in the blood of one or both parents and (2) a type M parent cannot have a type N child and a type N parent cannot have a type M child. Quite unrelated to these types are the iso-haemagglutinogens A and B so that there are three types in each blood group thus making possible 12 descriptions of blood, if only the original four groups are considered or 18 descriptions if sub-groups A_1 and A_2 are considered. It is also suggested that typing as well as grouping may be important in transfusion work.

F Murgatroyd

NAPIER (L. Everard) The Aetiology of Tropical Macrocytic Anaemia. —*Indian Med Gaz* 1939 Jan. Vol. 74 No 1 pp 1-8 With 6 charts. [21 refs]

Reviewing recent work the author points out that tropical macrocytic anaemia which may not represent a homogeneous group of diseases differs in a number of respects from pernicious anaemia. Apart from slight numbness and tingling of the toes and feet and diminished knee jerks neurological signs are universally absent in tropical macrocytic anaemia even of extreme severity while sore tongue and glossitis are also less common than in pernicious anaemia. The mean erythrocyte volume is high in both diseases but in the tropical anaemia the mean cell diameter is only slightly above normal suggesting spherocytosis and anisocytosis and poikilocytosis are less than in pernicious anaemia. The common slight initial reticulocytosis of pernicious anaemia is absent in uncomplicated tropical macrocytic anaemia and in the latter disease the author has not seen haemoglobinized megaloblasts in the peripheral blood and only rarely in the marrow. There is a lesser tendency to leucopenia and to shift to the right in the Arnetz count in tropical macrocytic anaemia than in pernicious anaemia. In the uncomplicated tropical anaemia there is said to be no increased bilirubinaemia and achlorhydria is not constant.

in this disease Yeast extract or marmite alone will produce a haemopoietic response and cure in tropical macrocytic anaemia whereas anahaemin so potent in pernicious anaemia sometimes fails even in massive doses the insoluble ammonium sulphate fraction of campolon, active in pernicious anaemia, is inactive in tropical macrocytic anaemia but the soluble fraction is active in both diseases as is campolon and other crude liver extracts. The author believes that in tropical macrocytic anaemia there is general hyperplasia of the red cell forming elements with excessive multiplication but delayed maturation at the megaloblast level or in other words interference with the normal development of the red cell occurs at a later stage than in pernicious anaemia. Such red cells being relatively more normal than those of pernicious anaemia are less susceptible to destruction by a normal reticulo-endothelial system and so in the uncomplicated tropical anaemia there is no excess bilirubinaemia. Where there is excessive haemolysis in tropical macrocytic anaemia the author agrees that reticulo-endothelial hypertrophy due to antecedent chronic malaria is the probable predisposing factor.

F Mergatroyd

EVANS (Barbara D F) & WILLS (Lucy) Red Cell Fragility in Tropical Macrocytic Anaemia.—*Jl Path & Bact* 1939 Mar Vol 48. No 2 pp 437-442 With 2 charts

The authors give the following summary —

(1) The uncorrected median corpuscular fragility in 40 cases of tropical macrocytic anaemia lay between 0.255 and 0.375 per cent NaCl, with a mean of 0.316 per cent. The normal mean of 0.306 per cent., determined by the same method, is significantly higher.

(2) The difference could be largely eliminated by applying a correction for anaemia the range in 39 of the above cases then becomes from 0.302 to 0.423 per cent NaCl, mean 0.356 per cent. The normal mean is only probably significantly higher than this corrected figure. The exclusion of all pregnant or recently delivered patients from the anaemia series made the difference between the mean M.C.F. of this series and that of the normal 0.0174 per cent NaCl, standard error 0.0063, a significant difference.

(3) The M.C.F. for mean and non-pregnant women was significantly lower than the M.C.F. of pregnant women but the number of pregnant women tested was small.

(4) It is suggested that pregnancy may result in an increased fragility masking the decrease which takes place in uncomplicated tropical macrocytic anaemia.

(5) Using the corrected figures for M.C.F. there was no correlation between the degree of anaemia and the value of this figure.

DIGGS (L W) & BRIB (Juanita) The Erythrocyte in Sickle Cell Anemia. Morphology, Size, Hemoglobin Content, Fragility and Sedimentation Rate.—*Jl Amer Med Assoc* 1939 Feb 25 Vol 112 No 8 pp 685-700 With 8 figs [16 refs.]

In sealed fresh preparations most of the cells are round or oval, although there may be a variable number of irregular elongated or pointed cells, but as the preparation stands and carbon dioxide increases cells expand and undergo transformation to bizarre multi-pointed forms. This may begin within an hour and is usually completed within twelve or twenty-four hours, the rate being increased if the blood is anovaemic. The commonest change is a rapid thickening

of the cell on one side with thinning of the disc on the opposite side the cell diameter becomes increased and the thinned out portion pointed while coincidentally the thickened portion becomes elongated and pointed filaments extrude from its ends and side condensation of the haemoglobin sometimes into several foci may occur. These preliminary changes occur within a few minutes and subsequent changes are slow. In other cells active kneading movements precede the formation of spicules while in others no visible movement occurs until the development of barbs of cytoplasm. If the preparation is exposed to air bizarre cells revert to round form if left sealed for some days all the cells become haemolysed or rounded up and finally disintegrated. The more mature cells sickle more readily than the less mature.

The most characteristic sickle cell is hyperchromatic elongated pointed at each end and curved in the middle and may be 50μ long and only 1 to 2μ broad the average size being from 10 to 20μ long and from 2 to 4μ broad. The number of typically sickled forms is highly variable in different patients and is not related to the severity of the anaemia. The size of the round erythrocytes in sickle cell anaemia is also highly variable ranging from as small as platelets to as large as neutrophils the average diameter being greater than normal. Reticulocytosis is common the average of forty two cases being 15 per cent. Fixed tissue preparations show sickled cells especially in the spleen and bone marrow and the distension of small capillaries by these cells may be a factor in the production of thrombosis which is a common feature of this disease. The average mean corpuscular volume of forty four cases was 90μ , the average mean corpuscular haemoglobin 29 $\gamma\gamma$ and the average mean corpuscular haemoglobin concentration 32 per cent. from which it was concluded that the erythrocytes in sickle cell anaemia are usually of the normocytic, normochromic type with a tendency toward macrocytosis. The erythrocytes are more resistant than are normal cells to hypotonic saline but less resistant to carbon dioxide and mechanical trauma. The sedimentation rate was variable.

Dr E. E. Osgood raised the question of differentiating true sickle cell anaemia from other anaemias in a negro with the sickle cell trait. He also stated that ovalocytosis or familial poikilocytosis occurs as commonly in white persons as in negroes has no association except accidentally with anaemia and can be distinguished from true sickle cell anaemia by the fact that the cells are really sausage shaped with rounded ends and the number of poikilocytes does not increase in an atmosphere of carbon dioxide or on standing in moist cover slip preparation. Dr L. W. Diggs stated that in true sickle cell anaemia typical oat and crescent forms can usually be found and are rarely observed in other blood dyscrasias. There is also leucocytosis thrombocytosis and evidence of abnormal regeneration of bone marrow. The reticulocytes are increased. The erythrocytes are more resistant to hypotonic saline. There is a history of chronic anaemia recurrent febrile illnesses with severe pains and important physical signs are jaundice cardiac enlargement hepatomegaly and ulcers of the legs. In the early stages the spleen is enlarged but later atrophied. Patchy osteoporotic and osteosclerotic changes occur in the long bones. Usually sickle cell anaemia is not confused with other anaemias but with some acute febrile illness. In addition to ovalocytosis where the cells do not undergo further change in moist preparations there is a

third type of abnormality characterized by elliptical cells which in moist preparations protrude points from their ends and become oat shaped. This resembles the sickle cell trait but should not be confused with it.

F Murgatroyd

PLAUT (Alfred B. J.) *Aplastic Anaemia. A Case Report.—South African Med J* 1939 May 13 Vol. 13 No 9 pp 324-327
With 1 chart.

A case of much interest, because such are rare but seem to be becoming less so not only in the tropics but in temperate climates also. The subject in this instance was a European 23 years of age, admitted to hospital for epistaxis. Soon after there were haemorrhages from nose throat gums ears melaena, and later haematemesis bleeding of the fundi and purpuric spots on legs and abdomen. Transfusion and haemostatics were practically ineffectual and death occurred 22 days after admission to hospital.

Agranulocytosis was a feature but the absence of anginous sore throat and of mucosal or other ulceration was against this as the basal diagnosis, as was the more marked degree of anaemia. The colour index in the early stage was above unity but fell gradually to 0.87. One particularly notable feature was the rapid reduction in platelets. A week after the patient's admission to hospital they numbered 213 000 per cmm but in less than a fortnight later were too few to estimate.

This case is referred to here because of the resemblance to onyala [see this *Bulletin* 1938 Vol. 35 pp 74 444 and 1939 Vol. 36 pp 157-160] though the characteristic blood blisters in the mouth were not seen. Treatment by intramuscular injection of whole blood has had excellent results in onyala, but was not tried in this case.

H H S

MOESCHL (Hermann) *Seltene Formen von hyperchromen Anämien. [Rare Forms of Hyperchromic Anaemia].—Wien Klin. Woch* 1939 Apr 21 Vol. 52 No 16 pp. 373-378. With 1 fig [13 refs.]

Several instances are here recorded in which the signs of hypochromic anaemia were a marked feature. Some were cases of pernicious anaemia, others were associated with ulcer of the stomach, with malignant disease and so forth but one was of interest from the view of the tropical practitioner. This was a man of 57 years who had served in India and had suffered from malaria and at one time from abdominal pain due to appendicitis and appendectomy had been performed. Symptoms typical of sprue now declared themselves and red cells numbered 1,330 000 per cmm Hb 35 per cent. C.I. 1.3 anisocytosis poikilocytosis, polychromasia, macrocytes and a few normoblasts were present. An unusual finding was gastric hyperacidity with the anaemia [but see this *Bulletin* 1923 Vol. 20 p 733 and 1924 Vol. 21 p 43]. Improvement followed the administration of liver and vitamins B and C.

H H S

TROWELL (H. C.) *Diagnosis and Treatment of the Common Anaemias of Uganda.—East African Med J* 1939 Mar Vol. 15 No 12 pp 402-418. [34 refs.]

Anaemia is probably so common in East Africa that few natives have a normal haemoglobin. Confusion may arise in the classification

of these anaemias because the average red cell of the East African native may be larger than that of the European and more work must be done on their normal and abnormal Price Jones curves. All observers are agreed however that the common anaemia is hypochromic. The most frequent cause appears to be hookworm infestation due exclusively to *N. americanus*. Hookworms produce anaemia by intestinal haemorrhage and if the anaemia is severe the occult blood test is always strongly positive even to several dilutions of the faecal suspension. The author believes that anaemia due to malaria is only common in persons with poor immunity, namely babies and adult immigrants; it should not be diagnosed in the absence of parasites whereas in hookworm anaemia there is iron loss. Many anaemias are however due to the operation of several different factors hookworms, malaria and dietary deficiency, none of which can at present be quantitatively assessed. For the hypochromic anaemias 20 grains of ferrous sulphate thrice daily is satisfactory. This salt is relatively stable in solution but a few minims of sulphuric acid are added to dissolve the small amount of ferric hydroxide produced and so preserve the appearance of the solution. [For a discussion of the cause of hookworm anaemia see this *Bulletin* 1937 Vol 34 pp 1-14] *F Murgatroyd*

MACDONALD (G) A Study of Anaemia affecting Labourers on Assam Tea-Estates.—*Indian J. Med Res* 1939 Apr Vol. 26 No 4 PP 1001-1040 [21 refs]

The author examined 9 042 persons on tea estates in Assam and found 10.42 per cent. of women 5.33 per cent of children and 2.77 per cent. of men with an average haemoglobin of less than 50 per cent as determined by Tallqvist's scale. He regards anaemia as the chief cause of the possible exception of malaria of sickness and death among the labourers and estimates that 3 000 working days and 6 lives per 1 000 persons *per annum* are lost because of it.

Contrary to common belief hookworm infection, although it may aggravate the severity or make cure more difficult does not appear to be the chief cause of the anaemia because the degree of infestation showed a lack of correlation with the severity of the anaemia and because the effects of antihelminthic treatment on the anaemia were variable [but see this *Bulletin* 1933 Vol. 35 p 278 and 1939 Vol. 36 p 324] Other possible causes were explored in an epidemiological study.

The staple diet is rice with the addition of dhal a pulse resembling the lentil, and small quantities of mustard seed oil some green vegetable and some form of animal protein are obtained by most people on one or more days of the week. Fat is deficient. The calcium intake is low and the P/Ca ratio high but the addition of calcium showed no therapeutic advantage the iron intake is above the normal standards. Carotene and vitamin A are very deficient and this explains the high incidence of phrynoderma xerophthalmia and night blindness other vitamins seem adequate. The rice is either home-pounded, retaining considerable quantity of pericarp and most of the germ or it is milled and before either of these processes it may or may not be parboiled. An experiment showed the mean haemoglobin value of women consuming one of the four possible varieties to be as follows home-pounded parboiled, 75.63 per cent. home-pounded

raw 71.72 per cent. milled raw 70.77 per cent. milled parboiled, 61.10 per cent. The difference between the home pounded parboiled and milled parboiled series is very highly significant that between the home-pounded parboiled and milled raw series is also significant. It was considered, however that the varying haemogenic properties of the rice were a subsidiary, and not the predominant cause of the prevailing anaemia.

The labour force consists of those settled on the estates and of short-term recruits. The former live at a reasonably good economic level whereas the latter despite good earnings, tend to live often because burdened by debts in their own countries on a pittance which may involve serious malnutrition but contrary to normally accepted belief the incidence of anaemia was approximately equal in the two groups. It was found however that anaemia was significantly more frequent among both groups on estates where there was a high proportion of newly recruited labour and this suggested the possibility of an infective cause for the anaemia. Although the spleen rate showed no correlation with the incidence of anaemia it was considered that malaria might be an operative factor through the admixture of different strains of parasites or some upset in the balance between transmission and immunity following the mixture of new recruits and settlers having varying degrees of immunity.

Two experiments were designed to test this hypothesis. In the first 42 anaemic women were treated with atabrin and small doses of iron, and they showed a highly significant increase in their haemoglobin compared with controls receiving only iron. In the second experiment a search was made for malarial parasites in placental films, since only a small percentage showed parasites in the peripheral blood but no significant correlation between anaemia and the presence of parasites was revealed.

Unfortunately the work was prematurely terminated but the results are highly suggestive and, should the connection between the anaemia and malaria be substantiated, reaffirm the importance of malaria control. In any case it seems desirable so far as possible to keep the old settled inhabitants and the new and temporary labourers segregated.

F Murgatroyd

GIGLIOLI (George) *Health Conditions on Sugar Estates.—Health Conditions on the British Guiana Sugar Estates 1938* Nov 21 Annexure 5 pp v-xxx With 8 diagrams & 2 plans.

To the Annual Report of the Surgeon-General, British Guiana for 1934 Dr Giglioli contributed an admirable survey entitled *Medical Reorganisation and Work on the Sugar Estates* of Blairmont, Bath and Providence [see this *Bulletin Supplement* 1936 p 228] in which he demonstrated that effective and economic preventive measures in the interests of public health can only be framed on the basis of data systematically collected over an adequate period of time. In the present paper Dr Giglioli continues these excellent studies but this time his observations are extended to cover all sugar estates in British Guiana.

Following brief references to climatic and topographical conditions and the relevant vital statistical facts characterizing the estate populations under review Dr Giglioli proceeds to the detailed discussion of the several features of sanitary organization and administration,

prevalent diseases causes of deaths etc. These descriptions are deserving of the most careful consideration for on the present occasion it is possible to do no more than to refer briefly to one or two sections of the Report under review

The 21 estate hospitals in British Guiana have bed accommodation for 1,246 patients each hospital being in charge of a *Sick-Nurse Dispenser*. It is pointed out that while Dispensers are unusually well qualified to carry out what should be their work *e.g.* dispensing—their clinical training is negligible yet on sugar estates and in rural districts in general the work of the dispenser is mainly clinical. He is expected to diagnose and treat cases decide which patients are to be admitted to hospital and which are to be seen by the Government Medical Officer but the great majority of patients the dispenser treats himself as Casual cases. In these circumstances Dr Giglioli observes that the accuracy of diagnoses must be treated with the greatest reserve and is of the opinion that from the medico-statistical point of view estate hospital records are of questionable value. *Malaria* which is the dominant health problem and directly or indirectly influences all other sanitary matters is reviewed at length in this *Bulletin*, 1939 Vol. 36 p 805 but it is pertinent to observe that during 1937 admissions to estate hospitals totalled 15,225 patients treated by G.M.O.s numbered 3 135 only while casual cases treated by Dispensers numbered 183,398. Among the cases treated were 42,311 of *malaria* and of these no less than 33 151 or about 79 per cent were treated as casual cases by Dispensers.

The notes on the *prevailing diseases* are based on experience for the six years ending 1937, and are presented at some length. It is noted that over the period *malaria* claimed an average of 157 deaths per annum and that *chronic nephritis* was also a serious cause of disability and death with an average of 102 deaths per annum. *Respiratory diseases* are prevalent but the low incidence of *tuberculosis* is noteworthy with an average of only 16 deaths per annum. *Nutritional diseases* are common amongst East Indians and *enteric fever* probably more widespread than available records would indicate.

Housing water supplies sewage disposal etc. are other important matters discussed by Dr Giglioli and for information on these matters the reader is referred to the Report itself P Granville Edge

BUTTLE (G. A. H.) *The Action of Sulphanilamide and its Derivatives with Special Reference to Tropical Diseases.*—*Trans Roy Soc Trop Med & Hyg* 1939 July 28. Vol. 33 No 2 pp 141-159 With 5 figs. [93 refs.] Discussion pp 160-168 [SINTON (J. A.) MAXSON BARR (P.) SHARP (N. A. Dyce) LEWTHWAITE (R.) FAIRLEY (N. Hamilton) FELIX (A.) & BUTTLE (in reply)]

Since the introduction of prontosil by Domagk in 1935 there have been few branches of medicine in which sulphonamide drugs have not been employed. The sulphonamide compounds so far employed in the chemotherapy of bacterial infections can be classified into two groups. From sulphanilamide itself are derived (a) compounds containing substituents in the amino group prontosil, rubiazol

proseptasme soluseptasine and prontosil soluble, (b) compounds containing substituents in the amide group uliron albucid and M. and B 663 Sulphone derivatives unrelated to sulphanilamide are rodfone and 4-4-diaminodiphenylsulphone the latter while more effective than sulphanilamide is unfortunately more toxic. The sulphonamide group of drugs has been employed in a number of tropical infections. There is no evidence that helminthic diseases are directly affected, but in filariasis improvement is due to curative action on the secondary streptococcal invaders. *Plasmodium knowlesi* in monkeys is susceptible to sulphonamide drugs but human malarial parasites are resistant except the asexuals of *P. falciparum*. Trypanosomes are unaffected but a number of bacterial diseases appear to be favourably influenced by sulphonamides more especially plague meningococcal and pneumococcal infections. Clinical results obtained in the treatment of typhoid and Brucella infections are less satisfactory while the only virus diseases which are in any way affected are small-pox, lymphogranuloma inguinale and trachoma, the corneal improvement in the last condition being more marked than that of the conjunctiva. The mode of action of the sulphonamide drugs is still uncertain. In the subsequent discussion, Dr N. A. Dyce Sharp reported that he had cured five consecutive cases of tetanus with prontosil, proseptasme or sulphanilamide given either by mouth or by intramuscular injection. Dr Lewthwaite reported failure to influence tsutsugamushi disease in guinea-pigs but thought sulphonamide drugs might be of value in treating the bronchitis and bronchopneumonia, which are common complications of human infections. Dr Felix stated that in the treatment of typhoid fever the sulphonamides had been disappointing. No good results had been obtained from the use of the drugs in combination with antityphoid serum.

- i. DIXONO (J. E.) Treatment of *Brucella melitensis* Infection with Prontosil.—*Brit Med J* 1939 Feb 18, pp. 326-327
- ii. BRITISH MEDICAL JOURNAL 1939 Feb 18, p. 342.—Chemotherapy in Undulant Fever

i. In view of the favourable reports published on the effect of sulphonamides in undulant fever [see also this *Bulletin* 1939 Vol. 35 p. 826 and 1939 Vol. 36 p. 157] the author attempted this treatment in 25 patients in Malta. In all cases the diagnosis was confirmed by agglutination reactions of over 1 in 100 and as *Brucella abortus* has not been found in Malta, all the infections may be regarded as due to *Br. melitensis*. In 12 blood culture was positive. Sixteen cases were of the ordinary type 4 of the malignant and 6 of the mild intermittent type. In 18 prontosil rubrum was used, in 4 prontosil album and in 3 streptococci. The average dose was 4.5 gm daily for 7 days but this was prolonged to 12 days in 4 instances and stopped early on account of intolerance in 5.

In 19 cases there was no apparent effect on the temperature or on the course of the disease in the other 6 (apparently successful) cases two relapsed (one died) one was a very mild case in one a very small dose was given and two recovered in the 8th and 17th week respectively. In 5 instances blood culture was attempted on the 7th day of treatment and in 4 of these it was positive in the fifth the culture was contaminated.

The author is therefore definitely of the opinion that these drugs are not useful in undulant fever in Malta and in view of the usually low mortality of the disease and the definite element of danger in sulphonamide therapy considers that its use is not justified.

ii. The Editorial points out that *Br abortus* may be more susceptible to chemotherapeutic attack than *Br melitensis* and that it would be unwise to compare too closely these findings based so largely on treatment with prontosil rubrum with others in which sulphanilamide was used since it is generally accepted that the latter has superseded the former. A plea is made for a further trial with sulphanilamide in a standardized system of dosage used in alternate cases. C IV

BYNUM (W Turner) Recurrences of Undulant Fever (Brucellosis) following the Administration of Sulfanilamide.—*Jl Amer Med Assoc* 1939 Mar 4 Vol 112 No 9 pp 835-836

Six cases are reported, two with acute one with subacute and three with chronic brucellosis. The diagnosis was confirmed either by agglutination or skin tests. Sulphanilamide was given in adequate doses but although improvement followed in three of the cases later relapses occurred. Two of the patients experienced no relief of symptoms and one seen first two weeks after finishing a heavy course of sulphanilamide for gonorrhoea was not given a further course. The author has not therefore been able to duplicate the satisfactory results reported by other workers. [See also this *Bulletin* 1938 Vol. 35 p 826 1939 Vol. 36 p 157 and DEBONO above] C IV

CONDELL (Lyle A.) Sulfanilamide in Treatment of Brucellosis.—*South Western Med* 1939 June Vol 23 No 6 pp 173-176

CLEMENTE (Giuseppe) Sulla vaccinoterapia delle Brucellosi con vaccino antimehitense Bruschettini [Treatment of Human Cases of Brucellosis with Bruschettini Vaccine].—*Riv Sanitaria Siciliana* 1938. Dec. 15 Vol. 26 No 24 pp 1436 1439-42 1445

The author speaks of 40 cases and gives notes of seven infected with *Br melitensis* in which other forms of treatment and other vaccines had been tried ineffectually but in which much benefit followed the use of a vaccine obtained from Bruschetti Laboratory of Genoa. In some it was administered intramuscularly the contents of a phial every 48 hours [but the actual dosage is not stated] in others intravenously. In all it was well tolerated, but the febrile response was more marked following *intra venam* injection. H H S

HOODLESS (D W.) Medical Education of Native Races.—*Fiji Ann Med & Health Rep for Year 1937* pp 30-32.

McGUSTY (V W T) Note on the Central Medical School in Suva in Relation to the Health Problems of the Pacific.—*Ibid* pp 33-35

HOODLESS (D W.) Report on the Central Medical School, Suva.—*Ibid* pp 36-40

Hoodless discusses the education of Fijians in general and remarks that a healthy youth if taken early enough and given equal facilities

can be educated to the same extent as a European youth. He gives a brief account of the history of medical education in Fiji. McGusty states that from its inception to the end of 1936 195 native medical practitioners have graduated from the Central Medical School. Emphasis is laid on the aim of the School to encourage the students to retain their native habits of living as far as possible. The course lays stress on operative surgery public health and preventive medicine. The formation of this school was only rendered possible by the pooling of the resources of the participating administrations.

Hoodless shows that in 1937 the average total cost per student was £74. In 1931 the course of study was extended from three to four years. Hospital duty is performed and lectures are given by members of the honorary staff. During the year 47 students and post-graduate students were in residence and the average number of Fijian students who qualify each year is four with an average annual loss of two. In Fiji there is one Native Medical Practitioner for every 1 600 of the native population. The first certificate was issued in 1888. [See, for fuller account this *Bulletin* 1936 Vol. 33 p. 828] C IV

DE LANGEN (C D) Medical Training in the Indies.—*Bull Colonial Indl Amsterdam* 1938 Feb. Vol 1 No 2 pp 125-134

Medical instruction was first given to natives in the Netherlands Indies at Batavia in 1851 with a view to training them as vaccinators. The course was gradually extended as it was realized that these persons would be expected to do more than vaccinate until now the medical school at Batavia attains full European standards and there is another school at Surabaya. The full course at Surabaya lasts 8 years and the graduates are fully qualified to practise in the Netherlands Indies, but not in Holland. It is intended to bring the standard at this school up to that of Batavia.

In addition to these fully qualified native doctors the authorities train subordinate assistants to act as nurses orderlies, laboratory assistants and the like. Since these persons are not regarded as fully qualified it is unlikely that they will bring discredit on western medicine by undertaking and failing to perform efficiently tasks beyond their capacity which might happen if a dual standard of qualification were permitted.

The author shows that modern hygiene has points in common with native custom but that western therapeutic measures are strange to the native mind, and urges that the traditional native methods of treatment, often based on experience handed down in families, should not too readily be dismissed by those with western education. He gives a warning against the use by students of advertisement literature in place of standard text-books. This practice is encouraged by the increasing amount of general pathology included in the pamphlets circulated free of charge to medical students by big business firms whose primary object is not the spread of accurate information.

The training of Asiatic medical men should be consciously directed in a manner that will fit them for their special task. The conditions differ in many respects from those which western medical men meet in Europe. [The same reasoning applies to the training of European medical men who intend to work among native races.] C IV

MARTIAL (J E) L'acclimatement des blancs en pays chauds Deux exemples les maures du Hodt et la colonisation pénale en Guyane [Acclimatization of White Races in Hot Countries].—*Ann de Méd et de Pharm Colon* 1938. Oct.-Nov.-Dec. Vol. 36 No 4 pp. 882-914 With 2 graphs.

The first part of this paper consists of a description of the climatic conditions of the French Sudan and Algeria. The second part commences by describing how by the formation of a suitable microclimate immediately next to the skin by regulation of clothing man is able to adapt himself to arctic and tropical conditions in this respect differing from plants and animals. But the diseases indigenous to tropical countries constitute a greater danger than climatic conditions.

In Europe the seasons during which the heaviest agricultural work is necessary are spring and autumn, when temperatures are moderate but in the Sudan the heavy work must be done after the first rains in May and June at which time the sun is strong and humidity high. The effects of sunstroke and of light reflected from water sand and other surfaces are briefly described. Humid heat is responsible for heat stroke. At 15°C. three-quarters of heat loss in man is by radiation from the skin and one-seventh by evaporation of sweat. As external temperature rises the loss by radiation diminishes and that by sweat evaporation increases. It is therefore obvious that the humidity of the surrounding air is the important factor. The author considers that intestinal disturbances may be attributable to chilling of the sweat during the night and that diarrhoea may result. The kidney and liver functions are disturbed.

Rainy seasons in the tropics usually coincide with hot seasons and thus the most favourable conditions for the spread of the great endemic diseases malaria, yellow fever and sleeping sickness are created. Mosquitoes require water for breeding and the abundant vegetation which follows rain offers the necessary protection from the sun to the pupae of tsetse flies. Plague bacilli are best preserved in fleas at a vapour tension of 1-10 mm. and a temperature of 20-25°C. and plague incidence is greatest in the hot wet seasons.

The author considers that the resistance of peoples to indigenous diseases is a result of hereditary transmission of immunity. He quotes the mild types of yellow fever and typhus which occur in communities long exposed to these diseases, the malaria of preimmunized races and conversely the acute tuberculosis which may occur in native races to whom it is comparatively new.

For the white races in the tropics certain precautions are essential. Houses must provide a suitable micro-climate with protection from the sun and from disease vectors. Verandahs thick walls double roof and mosquito netting should be insisted upon. Clothing should be light and should not prevent the evaporation of sweat. Diet should be largely vegetarian but transition from European diet should be gradual. Work in the open should not be undertaken in the hot damp season between the hours of 10 a.m. and 4 p.m. Prophylaxis against disease by avoidance of vectors and drug prophylaxis should be employed, and the vaccinations advised are discussed.

The author quotes the successful preventive measures applied by CASTELLANI in the Abyssinian war [see thus *Bulletin* 1938 Vol. 35 p 628] and by the Americans in Panama, but these were disciplined communities. He gives a brief account of certain customs of the peoples

of French Africa and shows how white races (including Moors) fare badly in those parts originally inhabited by negroes and vice versa. Negroes transported to Guiana show more resistance than whites. Man has not yet successfully overcome geographical barriers. [See also this *Bulletin* 1939 Vol. 38 p. 423.] C. II

ZIEMANN (Hans) *Wie erobert man Afrika für die weisse und farbige Rasse?* [Conquest of Africa for the White and Coloured Races].—31 pp. [Refs. in footnotes.] 1939 Leipzig Verlag von Johann Ambrosius Barth.

ZIEMANN (Hans) *Zum Problem der Akklimatisation der weissen Rasse in den Tropen* [The Acclimatization of the White Races in the Tropics].—Reprinted from *C. R. Congrès International de Géographie Amsterdam 1933* Vol. 2. Section IIIc pp. 357-364.

BERLIN (Ch.) *Purpura solaris.—Harefnah* Jerusalem 1939 Jan. Vol. 16 No. 1 [In Hebrew pp. 1-10 With 2 figs. English summary p. 1.]

The author describes 25 cases of a condition in which haemorrhagic spots of varying size and form appear on the skin sharply outlined and occurring on unprotected parts and particularly on the backs of the hands. They are not painful and disappear spontaneously in 5-10 days leaving no pigmentation. If pressure be made with the thumb-nail for example, on the affected skin a "purpuric line" appears in 15-20 seconds formed of approximated petechiae. The author believes that the condition is due to the sun's rays and suggests the name *purpura solaris*. [Nothing is said of the diet or mode of life of these patients: the description is allied to that of various pellagroid conditions.] R. H. S.

MARSH (Frank) *Experiments in Heatstroke in Iran.—Trans. Roy. Soc. Trop. Med. & Hyg.* 1939, Nov. 28. Vol. 32. No. 3 pp. 371-394. With 12 graphs. [11 refs.]

Continuing his work on experimental heat-stroke Dr Marsh tentatively formulates a number of important conclusions in the present paper.

The rabbit, exposed to extremely high external temperatures and unable to sweat, relies mainly on hyper-ventilation and salivation for loss of heat. But survival appears also to depend on the ability to establish a new equilibrium at a high body temperature. And this seems usually to come about without any increase in the internal heat production. Those animals which do not adapt themselves satisfactorily to the heat exhibit the usual rise in metabolism. An important factor conditioning the reaction of an animal seems to be acclimatization. Animals exposed to heat on a number of previous occasions lie quietly and accommodate themselves well.

A further important matter brought to the fore in this paper is the sensitivity of the brain to heat. Whilst brain tissue is undoubtedly amongst the tissues most sensitive to heat the author considers its

power of survival to be greater than is usually thought. The determining factor is the period of exposure of the brain to the high temperature.

Thus the effects of heat may involve other bodily processes more seriously before damage to the central nervous system. Of the physiological processes probably concerned, the author discusses the ability of the circulatory system to withstand high bodily temperatures.

The work reported points once again to the necessity for immediately cooling the heat stroke patient. It stresses also the importance of acclimatization.

J S Weiner

ALAIN (M) & DELBOVE (P) Note sur deux cas d'infection à *B. whitmorei* observés chez des jeunes enfants. [Two Cases of Molloidosis in Children.]—*Bull Soc Path Exot* 1939 Jan. 11 Vol. 32 No 1 pp 20-24

The first of the cases here described is that of a child of 4 years a European presenting fever and diarrhoea with glairy blood-stained stools to the number of 30 in 24 hours. The child's condition became gradually worse with insomnia prostration and at times delirium. Six days after admission she complained of pain in the parotid region. A blood culture yielded a growth of *Pf. whitmorei*. Death took place two days later.

The second was a boy of 2 years also with diarrhoea. He showed signs of congenital syphilis. The blood contained *P. falciparum*. Four weeks after admission to hospital without apparent cause the child suffered from diarrhoea. 15 glairy blood tinged stools daily and the temperature rose to 39-40°C. From the stools *Ps. pyocyanea* was isolated which was pathogenic for guinea-pigs. Ten days after the onset of the diarrhoea the child developed a left-sided parotitis and a blood culture yielded *Pf. whitmorei*. Death occurred ten days later.

In neither case could any source of infection be discovered and the authors draw the strange conclusion that molloidosis is not a primary specific disease but secondary and due to exaltation or mutation of a saprophytic *pyocyaneus* into an organism with high pathogenicity and capable of setting up all sorts of morbid conditions. H H S

BAJOLET Glossites épidémiques des pays chauds. [Epidemic Glossitis in Warm Climates]—*Rev Prat Malad des Pays Chauds* 1938, Oct 17th Year Vol. 18 No 10 pp 441-4 447-8 451

Epidemic glossitis has been reported from Senegal and Madagascar but has been found also in Algeria, Tunis and France. The Senegal form is seasonal from December to March in Senegal during spring and summer in North Africa. It begins as a bright red circular erosion on the dorsum of the tongue near the tip with a dusky margin. This spreads rapidly and confluence produces an appearance resembling geographical tongue. In acute cases the tongue resembles that of scarlet fever. The lesion is painless except in the acute cases when the inside of the cheeks may be affected. Fever is uncommon.

Parotitis and involvement of the lymphatic glands may ensue the latter persisting after the healing of the tongue. The lesions progress until the 6th or 7th day after which they retrogress and cure is complete in 10 to 15 days.

The Madagascar form resembles this and streptococci are always found. It is probable that the Senegal form is also due to this organism. Treatment with sodium borate is advised and prevention by personal cleanliness and the search for carriers is advocated. C IV

DEJOU (L.) Aspects cliniques de la lymphangite endémique des pays chauds. [Clinical Aspects of Endemic Lymphangitis in Hot Climates.]—*Rev Prat Malad des Pays Chauds* 1938 Sept. 17th Year Vol 18 No 9 pp 393-6 399-400 403-4 407-8 411

Endemic lymphangitis which is a streptococcal infection must be differentiated from the lymphangitis which occurs in elephantiasis. It is an acute condition in which cellulitis accompanies the lymphangitis and may occur as nodules which sometimes suppurate in the subcutaneous tissues along the course of the inflamed lymphatic vessels. The corresponding glands are affected. Symptoms suggest a preliminary septicaemic phase and this has been confirmed by the discovery of streptococci in the blood of eight of the patients. Pyaemia may occur and may be indicated by patches of cellulitis occurring in various parts of the body. Chronic skin disease is the common precursor of endemic lymphangitis and no doubt forms a favourable portal of entry for the streptococci.

Treatment of the skin lesions by antiseptics especially perchloride of mercury is the most satisfactory method of prevention. [See also *Bulletin of Hygiene* 1939 Vol. 14 p. 508.] C IV

MOVRESTRUC (E.) Action de la di (p-acétylamino-phényl) sulfone dans le traitement de la lymphangite tropicale. [Di (p-Acetylaminophenyl) Sulphone in the Treatment of Tropical Lymphangitis.]—*Bull Soc Path Exot* 1938 Oct. 12. Vol. 31 No. 8. pp 694-695

The success attending the use of prontosil in experimental streptococcal infections led the author and others to study several sulphur derivatives. One of these β -aminophenylsulphanide (also designated 1162 F) proved even more successful than prontosil when given in an oily suspension to rabbits and rats with streptococcal infections and was tried in Martinique for patients with tropical lymphangitis. Still pursuing the study they evolved di (p-aminophenyl) sulphone (1358 F) but this, when tested in streptococcal and pneumococcal infections in mice, proved too toxic for beneficial use. They finally prepared di (p-acetylamino-phenyl) sulphone (1399 F) to which in France is given the name Rodilone.

Brief details of three cases are given. All suffered from severe lymphangitis associated with painful erysipelatous conditions and fever. Four tablets (comprimés) of rodilone were given daily in each case. In two of the patients the fever dropped and pain ceased in 24 hours but treatment was continued for a week. In the other is the statement crisis soon took place and the patient went out cured a week after coming under treatment. The author concludes that for treatment of such cases 1399 F is a valuable addition to the physician's armamentarium. [Since it seems to be unaccompanied by any toxic

symptoms it might be tried in cases of filarial lymphangitis. Unfortunately no indication is given as regards the dose beyond 'quatre comprimés']

YOUNG (W A) & BROWN (Mary H S) A Case of Esthiomène at the Sewa Hadji Hospital, Dar es Salaam—*East African Med J* 1938. Nov Vol 15 No 8 pp 262-266 With 3 figs. on 2 plates. [14 refs.]

A short note concerning a native woman admitted to the hospital in Dar-es-Salaam, suffering from the genito-anal syndrome of lymphopathia venerea. No active antigen was available for cuti reaction but the clinical picture of elephantiasis and ulceration of the pudenda with extension into the perineum and into the para vaginal tissues can leave little doubt as to the diagnosis. No stricture of the rectum was found but breaking down buboes in the groins were present. There was a considerable degree of anaemia and a septic temperature. Operative interference having proved useless the woman died.

HEYNESSY (R. S F) Observations on Nephritis in Uganda Natives—*East African Med J* 1939 Jan Vol 15 No 10 pp 329-340

A fairly high incidence of albuminuria exists among non-nephritic hospital patients in Uganda and acute respiratory infections are responsible for a large number of these cases. Oedema may be misleading even when associated with urine which suggests nephritis as a cause. Of 34 such cases coming to post mortem none showed renal damage which could be held responsible for the condition and 20 could only be ascribed to nutritional oedema.

Cardiovascular hypertrophy is often absent in the proved nephritic patients and retinal lesions are extremely rare. Blood urea is often normal but the urea concentration test is valuable. The author gives an account of the pathological findings in a series of post mortem examinations and shows that kidneys of normal appearance removed from non renal cases often show proliferative glomerulitis and focal interstitial infiltrations. The common type of fatal nephritis shows proliferative hyalinizing glomerulitis but some resemble Russell's *nephritis acris* of *repens* variety.

The progress is often insidious and the author considers that the various infections especially pneumococcal to which the natives of Uganda are prone are probably aetiologically related to the local forms of nephritis.

C H

LAURENT (Damien) Les problèmes de l'enfance en Afrique Equatoriale Française (années 1935-38-37) [*Child Welfare Problems in French Equatorial Africa 1935-37*].—*Rev Méd et Hyg Trop* 1938 Mar-Apr & May-June. Vol 30 Nos 2 & 3 pp 57-86 121-146. With 15 figs. & 2 charts. [Summary appears also in *Bulletin of Hygiene*]

This paper is a record of two years' child welfare work in the Middle Congo (French Equatorial Africa). It is in two parts dealing respectively with social and medical problems.

Owing to the lack of vital statistics any estimate of infant mortality can only be approximate but the author considers that it is at least 50 per cent. for the whole region and in places as high as 80 per cent.

Women can be induced to attend antenatal clinics with fair regularity from the fifth month onwards, but the attention they receive is largely nullified by their unwillingness to come into hospital for labour owing to the strength of tribal customs. Nevertheless, antenatal clinics are of value because through them women establish contact with the dispensaries and bring their infants during the early weeks of life when the risks are high. Early visits to the homes by health visitors do much to prevent conditions such as tetanus, ophthalmia, sepsis of the cord and bronchopneumonia. Women are asked to bring their babies to the clinics at first twice weekly later once a week, and the greatest importance is attached to weight as a delicate index of health.

Starvation is an important cause of infant mortality. In the early weeks the breast milk is usually quite adequate but later through laborious work and underfeeding it is not. Unsuitable supplementary feeding is resorted to and the results are often disastrous. Cold leading to respiratory affections, is a common cause of death owing to the fact that the children are naked. Dirt leads to scabies and sores and secondary infections.

The native woman is not capable of feeding her child artificially. Consequently this must be done at the centres or in some cases prepared feeds are given to the mothers. Fortunately the native child, even if artificially fed in a somewhat rough and ready manner is remarkably free from digestive troubles. Clothing can be provided by voluntary effort and cleanliness inculcated by education of the mothers at the centres.

An account is given of the organization of the child welfare centres in the Bramaville district. Records show that out of 500 infants attending the centres regularly there was a mortality in the first year of 16 per cent.

The native infant of the Congo weighs at birth less than the European but this is made up by the end of the first month. Up to the end of the fourth month this advance is maintained, but later there is a slowing in the rate of increase and at the end of the first year the native child weighs less than the European.

Increase in height is a constant factor in the native child, and measurement is the most reliable method of ascertaining age.

Evidence of avitaminosis is found in arrested growth and oedema of the limbs. Infantile scurvy is not uncommon and rickets is one of the great scourges. Skin affections many of them the result of improper feeding are very prevalent.

Prematurity is of frequent occurrence. Syphilis is not the cause and the author attributes it largely to hard manual labour in the later months of pregnancy.

Respiratory diseases are of the first importance and are the cause of nearly half the infant mortality. Clothing does much to prevent them.

Malaria is universal after the first few weeks. Splenomegaly appears early and is found in 95 per cent. of the children from two to six years, after which it diminishes. Infants respond well to quinine which should be given only during febrile periods. The author recommends the hypodermic (not intramuscular) route for young infants.

Of the infectious diseases common in Europe, measles, whooping cough mumps chickenpox and poliomyelitis are met with. Of these

whooping-cough is the only one which is endemic and occurs throughout the year. Serious pulmonary complications of measles and whooping cough are rare. Venereal diseases and tuberculosis which are such a serious problem in women and children in civilized countries, are of much less importance in French Equatorial Africa.

This paper is illustrated by photographs and charts. It can be recommended to all who are interested in child welfare in Tropical Africa.

REVIEWS AND NOTICES.

PORTER (Annie) [D.Sc. Lond. F.R.S.S.Af. F.L.S. etc.] *The Larval Trematoda found in Certain South African Mollusca with Special Reference to Schistosomiasis (Bilharziasis)*—*Publications of South African Inst Med Res* 1933 Dec Vol. 8 No 42. 492 pp. With 83 plates 1 map & 1 fig.

With enforced interruptions this monumental work was carried through while the writer was still on the staff of the Witwatersrand University Johannesburg and before she joined that of the McGill University Montreal. Its primary aim was to determine the snails which were concerned with the spread of schistosomiasis in South Africa. But seeing that snails there contained many other cercariae than those of the schistosomes of man that some of these others were furcocercous and that well meaning folk after finding fork tailed objects in local water or in snails had condemned the water and inflicted unnecessary hardship in a country where bathing is no mere luxury clear descriptions of 102 cercariae found in local snails are given. Of these 89 are listed as new species including 16 of the 17 furcocercous forms found and the descriptions of these cercariae occupy 274 pages but even so not all found are dealt with it being felt that when material was insufficient for proper description it was better to give no name to perplex future workers trying to identify what they found.

The total number of molluscs examined mainly in the fresh state was nearly 7000 belonging to 28 species a solid foundation for conclusions. One of these last is that there is individuality even in snails and experimental animals of the same species another way of expressing variation in nature. Thus an already infected snail rarely attracts miracidia of the same or other fluke species indeed in only eight of the snails examined were there larval trematodes of two species and individual rats vary so much in their reactions to infection that wrong conclusions may be drawn unless the habits and manners of each rat are already known. Another aspect of variability lies in the adaptation of young flukes to different snails. Thus in South Africa *S. haematobium* specially favours *Physopsis africana* but will also use *Ph. globosa*, *Bulinus tropicus* and *Lymnaea natalensis* again *S. mansoni* there uses *Planorbis pfeifferi*, *Ph. africana* and *B. tropicus* and *S. japonicum* has been found in two specimens of *L. natalensis* collected at the same time. There is in nature a constant association of the less susceptible with the more susceptible of these snails, and thus adaptability comes into action when the more susceptible species at that spot are already infected. Egg sizes are strikingly variable.

Among 1050 eggs of *S. haematobium* measured, the lengths varied from 80μ to 185.7μ , with most between 113μ and 133μ the widths were as variable. Next are described the egg of *S. spindale* with the larva bred in *Pl. pfeifferi* and of *S. bovis* with the larva bred in *Pl. africana*.

On the chemical and biological side it is shown that soapy water does not kill cercariae quickly enough to prevent their finding safety in the skin, that viable eggs have been found in soil, that a relatively short storage in urine or faeces kills them, and that drainage of marshy land has stopped infection. The route of entrance of miracidia varies in South Africa. Thus *Miracidium haematobium* preferably gains entrance into the snail by the respiratory opening but with such as penetrate the tentacle there are minute ripples lasting a few minutes which seem to mark its progress down this. *M. mansoni* however preferably attacks the tentacles causing tubercles and, it may be permanent deformity of these. The life of infected snails, as observed in the laboratory is much shortened (presumably by that destruction of the digestive gland which is figured) and the snails are sterilized by growth of young flukes in their gonads. The copious and excellent illustrations are nearly all from drawings and a map of the Union stippled to show the range of human infections, bears the legend that the distribution of molluscan hosts is much more extensive—a significant reminder of possibilities as ease of communication increases.

The writer points out the implications of the life-histories and leaves the application to medical men but at the same time she tells this significant story. The children in a small Indian settlement in the Union were interested in her snail collecting were told how the bad water made them itch, and were shown under the microscope cercariae coming out of snails. shortly the mothers came along and were told it all again, with stress thrown on the infection of the water. Next time she went that way she found that some of the pools had been filled in, others had been deepened, all the snails the people could collect had been burned, and the men had deepened the wells for drinking water.

In this monograph is summed up the investigations of thirteen years. It is a fine foundation for local work, a valuable pointer for work elsewhere in the world, and a stimulus as to what can and should be done there. For instance is not the rarity of double infections of snails a hint of the possibility (in certain conditions and perhaps as a second line of defence) of producing in them an infection by a larval fluke which does not live in man and if possible an infection heavy enough to kill or at least to sterilize the snails? There is in this monograph much to provoke thought and aid effective action.

Clayton Lane

GOTKARD (Pierre) [Chirurgien des Hôpitaux d'Alger] Pathologie chirurgicale de la rate. [Surgical Pathology of the Spleen].—174 pp. With 4 figs & 11 plates. 1909. Paris. Masson et Cie. 120 Boulevard Saint-Germain. [35 fr.]

This is a timely review of the present position of the surgery of the spleen for as the author points out the progress of treatment of leucæmia by radiotherapy and the modern curative treatments of pernicious anaemia and kala azar have reduced the former indications for splenectomy.

The comprehensive character of the book will appear from the fact that the injuries and diseases of the spleen are dealt with under twenty two sections. Ptoses torsions of the pedicle and injuries and ruptures are first dealt with in all the more serious forms of which splenectomy is indicated. Rupture of malarial spleens is of special interest to workers in the tropics and its operative mortality is placed at about 40 per cent. which is higher than in some Indian series of cases. Under abscess of the spleen the common tropical form due to amoebiasis is only referred to and its successful treatment by aspiration and emetine is not mentioned. In the septic cases prevalent in cooler climates the mortality is placed at 80 per cent.

Some two-thirds of the book are taken up with the interesting and difficult subject of the many varieties of splenomegaly. Clinical descriptions diagnosis prognosis and treatment of each are given and form a valuable contribution to the subject as the author throughout has adopted a critical attitude regarding the resort to splenectomy for many of the forms of enlarged spleen for which it has from time to time been advised and used. In fact the only class of case for which he unreservedly claims it as a surgical triumph is haemolytic jaundice. Other splenic conditions in which it may be recommended in carefully selected cases are purpuric conditions the forms of enlarged spleen in which splenectomy was originally advised by Banti splenic anaemia and Gaucher's disease and then only in the more severe types in which the prognosis under medical treatment is grave. The different varieties of cirrhosis of the liver are next dealt with. In the atrophic cirrhosis of Laennec operative procedures are ruled out. On the other hand splenectomy may sometimes be advisable in Hanot's hypertrophic cirrhosis in the presence of severe haemorrhages and anaemia although relapses occur and the ultimate prognosis is bad. The same applies to grave forms of gastro-intestinal haemorrhages without ulceration.

The last section of the book deals with surgical procedures by far the most frequent and important of which is splenectomy which is simple in the case of comparatively small unadherent organs but grave under the reverse conditions. This part of the subject is illustrated and should prove of as much service to surgeons in the tropics as other portions will be to physicians who have to advise patients regarding the possibilities of obtaining surgical relief in this difficult class of diseases. The book is well printed and in the usual paper cover of French works.

LEWIS'S MEDICAL AND SCIENTIFIC LIBRARY Catalogue of Lewis's Medical & Scientific Lending Library Part II.—Classified Index of Subjects and Authors. New Edition. Revised to the end of 1937.—156 pp 1939 London H. K. Lewis & Co Ltd. 136 Gower Street W.C.1 [Pts. I & II complete 16s (to Subscribers 8s)] [Review appears also in *Bulletin of Hygiene*]

Part II of Lewis's Library Catalogue revised to the end of 1937 provides a classified index of the subjects covered by the Library with the names of authors who have written upon them. The compilers have not adopted any elaborate theoretical system of classification but have followed the practical course of listing the names of the authors of the 20 000 or so volumes in the Library under appropriate main subject headings arranged alphabetically, adding the dates of

publication and in some cases a word or two in brackets to indicate the particular aspects of the main subjects with which the books deal. From this information a reader can readily ascertain the names of authors who have written on a particular subject, and can then, by referring to Part I of the Catalogue already published (see this *Bulletin* 1939 Vol. 38 p. 182) obtain the full titles and some further information about the books *s.e.* their price and size. Thus Parts I and II of the Catalogue together besides providing subscribers with the titles of books available in Lewis's Library form a most valuable classified guide to English published books on medical and technical subjects.

[No. 12]

TROPICAL OPHTHALMOLOGY

A REVIEW OF RECENT ARTICLES XXXIV *

Trachoma—Some of the problems presented by the disease have been discussed by TABORISKY.¹ This observer has had an exceptional experience of trachoma in Palestine both amongst the school-children and the general population. He admits that competent ophthalmologists might disagree regarding the diagnosis of any particular case of trachoma in the early stage the progressive development of a deep conjunctival inflammation (hyperaemia thickening and papillary hypertrophy) followed later by the formation of follicles is however characteristic. In heavily infected areas the virus on occasion may reach the eye in such small quantity or with such attenuated virulence as to produce no reaction more often in such cases it may induce an inflammation which heals spontaneously or becomes chronic. A relative immunity may occasionally be present and should this be overcome a true trachoma though slight or atypical may develop.

BURNET CUÉNOD and NATAF² have noted how closely the cell inclusions found in trachoma resemble those seen in lymphogranuloma and suggest that those drugs which are useful in the experimental form of the latter disease might prove equally serviceable in the case of the former. They have therefore employed diammodiphenylsulphone in the treatment of trachoma and have recorded their results. These appear to be fairly promising and the authors consider they have made a step forward in the treatment of the disease. CHANG³ has treated eighty cases of trachoma with ten per cent. solution of quinine sulphate according to the method described by SELINGER and has formed a favourable opinion of its efficacy. The solution is rubbed for one minute into the conjunctiva by means of a cotton applicator. The treatment is carried out twice weekly at first and the sittings

² BURNET (Et.) CUÉNOD (E.) & NATAF (R.) Essai de chimiothérapie du trachome par un dérivé glycosé du "4-4 diammodiphenylsulphone" efficace sur le pannus trachomatieux.—*Arch. Inst. Pasteur de Tunis* 1939 Mar. Vol. 23. No. 1 pp. 11-23.

³ CHANG (S. P.) Clinical Experiences with Quinine Treatment of Trachoma.—*Chinese Med. J.* 1939 May Vol. 55 No. 5. pp. 439-447

gradually reduced later. Some patients were found hypersensitive to the quinine and these developed an eczematous condition of the lids which subsided on ceasing the treatment.

STEWART⁴ has come to the conclusion that trachoma is caused by a virus whose most conspicuous form is the Prowazek Halberstaedter inclusion body. A free extra-cellular stage (the initial body) also exists: this resembles a pleomorphic bacterium. The initial body enters the cytoplasm of an epithelial cell and increases in size: several such may coalesce and form the kidney-shaped mass known as the Prowazek Halberstaedter body. Elementary granules which stain red with Giemsa subsequently appear in this body. Initial bodies both extra-cellular and intra-cellular stain a dark blue with Giemsa. Filtration through collodion membranes impermeable to bacteria is uncertain but the virus can be concentrated on the upper surface of such membranes. Baboons and grivet monkeys are susceptible to infection. The virus is killed by drying and infected cloths are dangerous for a short time only. The rôle played by lice in spreading the disease requires further investigation.

Assuming trachoma to be a Rickettsia infection POSTIC⁵ has continued the researches of DEREAC on the presence of the Weil-Felix reaction in trachoma. He obtained a positive reaction in 68 per cent. of trachomatous patients against a positive rate of 32 per cent. in non-trachomatous eye patients. One hundred and twenty cases of trachoma were tested and twenty five controls. TRAFESONTZEW⁶ believes that the Rickettsia found in the gut of lice inoculated with trachomatous material have no connexion with trachoma but are merely incidental. POLERY⁷ claims to have successfully cultivated trachoma Rickettsia *in vitro* by using tissue culture. Human placenta was found a suitable tissue but he suggests that corneal tissue obtained from a foetus or a recently deceased person might prove even more effective. Thin shavings of infected conjunctiva must be used for implantation mere scrapings are insufficient. The beneficial effect on the disease of an absence of such deleterious factors as scorching sun, heat, smoke and dust-laden winds has been noted by MOTAIS⁸. He had charge of 5 000 Tonkinese coolies working on rubber plantations in Cambodia and Cochinchina and found that only 0.5 per cent. showed signs of trachoma, whereas in Tonking their native country from 50 to 80 per cent. of the population is stated to be affected. The coolies were, of course medically inspected before recruitment, but even so the difference is striking and Motais believes that the favourable climatic conditions may be largely responsible.

⁸ MOTAIS (F.) Un changement de terrain et de conditions d'existence, peut-il ténifier la virulence de l'endémie trachomatose?—*Rev. Internat. de Trachome* 1939, Apr. Vol. 16, No. 2, pp. 88-92.

Glaucoma—Some points concerning *Epidemic Dropsy Glaucoma* have been recorded by KIRWAN.⁹ The disease is painless and all the more dangerous in consequence it usually occurs in the later stages of epidemic dropsy but may be accompanied by only mild signs of the constitutional disease if the intra-ocular capillary epithelium is specially susceptible to the toxin. Dietetic and medicinal treatment is unsuccessful and eserine is actually dangerous. Operative treatment is unnecessary as long as the visual fields remain unimpaired but it should be immediately adopted when field defects appear. A modification of Lagrange's operation is recommended as Elliot's operation though temporarily successful was often found liable to be followed by late complications. BHADURI¹⁰ advocates early recognition of the disease and stresses the importance of haloes as a warning symptom. He has found pilocarpine in two per cent. and four per cent. solution useful and has adopted Lagrange's operation with encouraging results.

Cataract—A review of the intracapsular operation for cataract has been made by BUXTON.¹¹ The opinions of many authorities are quoted by the author who himself had considerable experience at the Shikapur clinic. He prefers the classical operation and employs a corneo-scleral suture capsulotomy with Vogt's capsule forceps anterior chamber irrigation and peripheral iridectomy. He concludes that though the intracapsular operation may possess some advantages it involves an increased risk of certain complications. It may however be preferable for selected cases in such countries as India, where patients who require it are unlikely to return for a capsular discussion. The *Bulletin of the Ophthalmological Society of Egypt*¹² for the year 1938 records the proceedings of the Thirty fifth Session of the Society. The subject of retinal detachment led to an active discussion in which many members took part. Dr MAX MEYERHOF described some cases of sellar tumour which appeared to benefit from X ray treatment but he expressed the opinion that operation is the only sure therapeutic measure in the majority of the cases. Dr M. M. BAKRY claimed some striking successes in the treatment of optic atrophy by retrobulbar injections of atropin combined with measures taken to reduce the intraocular pressure together with suitable constitutional treatment.

PLAGUE.

PRÉCIS OF ABSTRACTS IN THIS SECTION

ANG *et al* (p 960) describe how in Fukien plague spread from the along the waterways to the interior. Small epidemics occurred after year to diminish after a decade but sporadic cases were in the interepidemic periods. The sanitary condition of many

Chinese towns is bad and rat infestation constant. Fumigation and poison bait are used and for shops the division of rat proofing measures to protect the three categories, bulk stock, replenishment stock and retail goods proved economically successful. The military authorities co-operated with the civil in an excellent organization.

RAO (p. 962) believes that plague is endemic, though frequently not recognized in Calcutta and suggests a systematic examination of the rodent population and an estimation of its relative immunity.

SURINI (p. 962) traces the history of plague in S. America. Anti plague measures in the ports have been conducted on well-known lines and in some instances have reduced the rat population by 70 per cent. ALFARADO and DE LA BARRERA (p. 962) report that in the Argentine sylvatic plague epizootics appear in winter and fade out in spring. Human infection is not common but may take the pneumonic form.

CASTELLANI (p. 963) describes a medium containing glycerol and rhamnose for the differentiation of *P. pestis* from *P. pseudotuberculosis rodentium*. RAO (p. 963) shows that the plague bacillus requires certain amino-acids for growth, but accessory growth factors are not essential.

TUMANSKY (p. 964) shows that *Proteus vulgaris* is antagonistic to *P. pestis* and this may account for the rapid disappearance of the latter in decomposing corpses, but plague bacilli can remain alive and virulent in rat or guinea-pig cadavers for 10 months or even longer in bone marrow uninfected by *Proteus*. RUSSO (p. 964) shows that virulence was not modified and considers that acari, which live on unimmunized rats, may become infected.

BREININGER (p. 964) relates the action of calcium chloride on *P. pestis* under various conditions. FAVORISKOVA (p. 965) describes the effect of phage on cultures of *P. pestis*.

RUSSO (p. 965) states that flesh eating flies of the genus *Sarcophaga*, in all stages of development, offer favourable conditions to the multiplication and diffusion of plague bacilli.

In Kenya, ROBERTS (p. 965) shows that the most important factor in the incidence of plague is the density of the *R. rattus* population. He (p. 965) reports that a high mortality in *field* rodents in Kenya was due not to plague but to Rift Valley fever. In the absence of proof it appears wrong to attribute outbreaks of plague in man to field rodents and their fleas.

VAN CAMPEKHOUT (p. 966) states that *Manomys aegandas* is a carrier of sylvatic plague in the Congo but *R. rattus* plays no part.

LOBANOV and FEDOROV (p. 966) note a distinct seasonal difference in the reaction of gerbils to plague infection. KORONKOVA *et al* (p. 967) conclude that agglutination reactions in *spermophiles* are not likely to be valuable in determining the epidemiology of plague.

In Western Canada GIBSON (p. 967) reports that no plague infection was found in 3,569 wild rodents and 7,582 rodent fleas examined. No infection with *Rickettsia dermatitidis* was found in a large number of ticks, but several were infected with *Bact. tularensis*.

JELLISON (p. 968) shows that predatory species of birds may transport flea infested rodents and may serve as accidental hosts of rodent fleas.

ESKEY and HAAS (p. 968) show that the fleas of wild rodents and of domestic rats are equally capable of becoming infected. They may harbour virulent plague bacilli in the gastrointestinal tract for as long as 130 days before becoming infective. For determining plague in

wild rodents the most effective method is the inoculation of the bodies of captured fleas into guinea pigs. The fleas should be killed by HCN and transmitted to the laboratory in 2 per cent salt solution DEVIGNAT (p 969) uses Broquet's medium (calcium carbonate 2, glycerin 20 distilled water 80) for clearing fleas for examination. This prevents putrefaction but ensures the survival of the bacilli up to six days so that they may be isolated for bacteriological examination. MURDOCK (p 969) records an outbreak of pneumonic plague in nurses attendants and doctors following the admission of a patient to hospital. Of 16 affected 15 died.

In a child described by FARINAUD (p 970) streptococci and later Gram negative bacilli were found in buboes. Inoculated guinea pigs died of acute plague and the streptococci were of low virulence.

Mice which ingested M & B 693 to the amount of about 2 mgm per gm. weight daily and which were inoculated with 10 000 lethal doses on the 5th or 6th day ingestion of the drug being continued thereafter survived. DURAND (p 970) reported that larger infecting doses often proved fatal but even then the bacilli could not be recovered from the dead animals. Most of the surviving animals showed considerable immunity. SCHUTZE (p 971) shows that white mice are less resistant to plague than white rats. M & B 693 soluseptasine and sulphone were given before or with the infection to these animals and it was found that M & B 693 was the most successful. Serum prepared against the Otten living vaccine was about equal to M & B 693 in prophylaxis and the author suggests that a combination of these might be better than either alone. GIRARD and GIRARD (p 971) found M & B 693 to be as efficacious as plague serum in the treatment of infected mice and guinea pigs.

BEARGAVA (p 971) gives advice on the protection of coolie workers in an anti plague campaign. JAMES (p 972) considers that the vigorous measures taken prevented an outbreak in the Mawchi mines in India. BABENUSHEV *et al* (p 972) show that fumigation of the burrows of ground squirrels with chloropicrin or calcium cyanide though not entirely eradicating the fleas in the burrows reduces their numbers. TIFLOV and POTAPOV (p 973) found that the majority of all species of rodent fleas in Russia migrate from burrows of field rodents when these are abandoned. TROTTER (p 973) remarks on the successful use of poison bait and other anti rat measures in Hawaii.

The Eastern Bureau of the Health Organisation of the League of Nations (p 973) reports that in India plague has steadily declined in the last 10 years. The same is true of the Dutch East Indies where the decline has coincided with mass inoculation by Otten's living avirulent vaccine. To be successful fumigation should be repeated every 3 months. ROSIER (p 974) attributes the decline of plague in Java, of which he gives figures firstly to the use of the living vaccine of Otten of which over 6 million inoculations have been given since 1935 and secondly to the campaign of house improvement. SCHUTZE (p 974) reports on field trials of vaccines in Java. With heat killed vaccine no superiority of virulent strains over avirulent or of smooth over rough was seen but for maximal protection of rats it is essential that the vaccine be grown at 37°C at which temperature envelope antigen production is highest. In mice however envelope antigen is not so important. The superiority of smooth avirulent living vaccine depends on the capacity for survival in the inoculated animal a rough strain is more quickly suppressed.

Chinese towns is bad and rat infestation constant. Fumigation and poison bait are used and for shops the division of rat-proofing measures to protect the three categories bulk stock, replenishment stock and retail goods proved economically successful. The military authorities co-operated with the civil in an excellent organization.

RAO (p. 962) believes that plague is endemic, though frequently not recognized, in Calcutta and suggests a systematic examination of the rodent population and an estimation of its relative immunity.

SUSSINI (p. 962) traces the history of plague in S. America. Anti plague measures in the ports have been conducted on well-known lines and in some instances have reduced the rat population by 70 per cent. ALFARADO and DE LA BARRERA (p. 962) report that, in the Argentine, sylvatic plague epizootics appear in winter and fade out in spring. Human infection is not common, but may take the pneumonic form.

CASTELLANI (p. 963) describes a medium containing glycerol and rhamnose for the differentiation of *P. pestis* from *P. pseudotuberculosis rodentium*. RAO (p. 963) shows that the plague bacillus requires certain amino-acids for growth but accessory growth factors are not essential.

TUMANSKY (p. 964) shows that *Proteus vulgaris* is antagonistic to *P. pestis* and thus may account for the rapid disappearance of the latter in decomposing corpses, but plague bacilli can remain alive and virulent in rat or guinea pig cadavers for 10 months or even longer in bone marrow uninfected by *Proteus*. RUSSO (p. 964) shows that virulence was not modified and considers that acari which live on mummified rats, may become infected.

BREINTYGER (p. 964) relates the action of calcium chloride on *P. pestis* under various conditions. FAVORISKOVA (p. 965) describes the effect of phage on cultures of *P. pestis*.

RUSSO (p. 965) states that flesh eating flies of the genus *Sarcophaga*, in all stages of development offer favourable conditions to the multiplication and diffusion of plague bacilli.

In Kenya, ROBERTS (p. 965) shows that the most important factor in the incidence of plague is the density of the *R. rattus* population. He (p. 965) reports that a high mortality in field rodents in Kenya was due not to plague but to Rift Valley fever. In the absence of proof it appears wrong to attribute outbreaks of plague in man to field rodents and their fleas.

VAN CAMPENHOUT (p. 966) states that *Maxomys wglas* is a carrier of sylvatic plague in the Congo but *R. rattus* plays no part.

LOBANOV and FEDOROV (p. 966) note a distinct seasonal difference in the reaction of gerbils to plague infection. KOROSKOVA *et al.* (p. 967) conclude that agglutination reactions in spermophils are not likely to be valuable in determining the epidemiology of plague.

In Western Canada GIBBONS (p. 967) reports that no plague infection was found in 3,560 wild rodents and 7,582 rodent fleas examined. No infection with *Rickettsia dermatroxenus* was found in a large number of ticks, but several were infected with *Bact. tularensis*.

JELLISON (p. 968) shows that predatory species of birds may transport flea infested rodents and may serve as accidental hosts of rodent fleas.

ESKRY and HAAS (p. 968) show that the fleas of wild rodents and of domestic rats are equally capable of becoming infected. They may harbour virulent plague bacilli in the gastrointestinal tract for as long as 130 days before becoming infective. For determining plague in

wild rodents the most effective method is the inoculation of the bodies of captured fleas into guinea-pigs. The fleas should be killed by HCN and transmitted to the laboratory in 2 per cent salt solution. DEVIGNAT (p 969) uses Broquet's medium (calcium carbonate 2 glycerin 20 distilled water 80) for clearing fleas for examination. This prevents putrefaction but ensures the survival of the bacilli up to six days so that they may be isolated for bacteriological examination.

MURDOCK (p 969) records an outbreak of pneumonic plague in nurses attendants and doctors following the admission of a patient to hospital. Of 16 affected 15 died.

In a child described by FARINAUD (p 970) streptococci and later Gram-negative bacilli were found in buboes. Inoculated guinea-pigs died of acute plague and the streptococci were of low virulence.

Mice which ingested M & B 693 to the amount of about 2 mgm per gm weight daily and which were inoculated with 10 000 lethal doses on the 5th or 6th day ingestion of the drug being continued thereafter survived. DURAND (p 970) reported that larger infecting doses often proved fatal but even then the bacilli could not be recovered from the dead animals. Most of the surviving animals showed considerable immunity. SCHÜTZE (p 971) shows that white mice are less resistant to plague than white rats. M & B 693 soluseptasine and sulphone were given before or with the infection to these animals and it was found that M & B 693 was the most successful. Serum prepared against the Otten living vaccine was about equal to M & B 693 in prophylaxis and the author suggests that a combination of these might be better than either alone. GIRARD and GIRARD (p 971) found M & B 693 to be as efficacious as plague serum in the treatment of infected mice and guinea-pigs.

BHARGAVA (p 971) gives advice on the protection of coolie workers in an anti plague campaign. JAMES (p 972) considers that the vigorous measures taken prevented an outbreak in the Mawchi mines in India.

BABENTISHEV *et al* (p. 972) show that fumigation of the burrows of ground squirrels with chloropicrin or calcium cyanide though not entirely eradicating the fleas in the burrows, reduces their numbers. TIFLOV and POTAPOV (p 973) found that the majority of all species of rodent fleas in Russia migrate from burrows of field rodents when these are abandoned. TROTIER (p 973) remarks on the successful use of poison bait and other anti-rat measures in Hawaii.

The Eastern Bureau of the Health Organisation of the League of Nations (p 973) reports that in India plague has steadily declined in the last 10 years. The same is true of the Dutch East Indies where the decline has coincided with mass inoculation by Otten's living avirulent vaccine. To be successful, fumigation should be repeated every 3 months. ROSIER (p 974) attributes the decline of plague in Java, of which he gives figures firstly to the use of the living vaccine of Otten of which over 6 million inoculations have been given since 1935 and secondly to the campaign of house improvement. SCHÜTZE (p 974) reports on field trials of vaccines in Java. With heat killed vaccine no superiority of virulent strains over avirulent or of smooth over rough was seen but for maximal protection of rats it is essential that the vaccine be grown at 37°C at which temperature envelope antigen production is highest. In mice however envelope antigen is not so important. The superiority of smooth avirulent living vaccine depends on the capacity for survival in the inoculated animal a rough strain is more quickly suppressed.

Chinese towns is bad and rat infestation constant. Fumigation and poison bait are used and for shops the division of rat proofing measures to protect the three categories bulk stock, replenishment stock and retail goods proved economically successful. The military authorities co-operated with the civil in an excellent organization.

RAO (p. 962) believes that plague is endemic, though frequently not recognized, in Calcutta and suggests a systematic examination of the rodent population and an estimation of its relative immunity.

SUSSINI (p. 962) traces the history of plague in S America. Anti-plague measures in the ports have been conducted on well known lines and in some instances have reduced the rat population by 70 per cent. ALVARADO and DE LA BARRERA (p. 962) report that in the Argentine sylvatic plague epizootics appear in winter and fade out in spring. Human infection is not common but may take the pneumonic form.

CASTELLANI (p. 963) describes a medium containing glycerol and rhamnose for the differentiation of *P. pestis* from *P. pseudotuberculosis rodentium*. RAO (p. 963) shows that the plague bacillus requires certain amino-acids for growth, but accessory growth factors are not essential.

TUMANSKY (p. 964) shows that *Proteus vulgaris* is antagonistic to *P. pestis* and this may account for the rapid disappearance of the latter in decomposing corpses, but plague bacilli can remain alive and virulent in rat or guinea-pig cadavers for 10 months or even longer in bone marrow uninfected by *Proteus*. RUSSO (p. 964) shows that virulence was not modified and considers that acari which live on mummified rats, may become infected.

BREITINGER (p. 964) relates the action of calcium chloride on *P. pestis* under various conditions. FAVORISKOVA (p. 965) describes the effect of phage on cultures of *P. pestis*.

RUSSO (p. 965) states that flesh eating flies of the genus *Sarcophaga*, in all stages of development offer favourable conditions to the multiplication and diffusion of plague bacilli.

In Kenya, ROBERTS (p. 965) shows that the most important factor in the incidence of plague is the density of the *R. rattus* population. He (p. 965) reports that a high mortality in field rodents in Kenya was due not to plague but to Rift Valley fever. In the absence of proof it appears wrong to attribute outbreaks of plague in man to field rodents and their fleas.

VAN CAMPENHOUT (p. 966) states that *Mastomys ugandae* is a carrier of sylvatic plague in the Congo but *R. rattus* plays no part.

LOBANOV and FIDOROV (p. 966) note a distinct seasonal difference in the reaction of gerbils to plague infection. KUSOBKOVA *et al* (p. 967) conclude that agglutination reactions in spermophils are not likely to be valuable in determining the epidemiology of plague.

In Western Canada GIBSONS (p. 967) reports that no plague infection was found in 3,569 wild rodents and 7,582 rodent fleas examined. No infection with *Rickettsia dermatitoxenus* was found in a large number of ticks, but several were infected with *Bact. tularensis*.

JELLISON (p. 968) shows that predatory species of birds may transport flea infested rodents and may serve as accidental hosts of rodent fleas.

ESKIN and HAAZ (p. 968) show that the fleas of wild rodents and of domestic rats are equally capable of becoming infected. They may harbour virulent plague bacilli in the gastrointestinal tract for as long as 130 days before becoming infective. For determining plague in

wild rodents the most effective method is the inoculation of the bodies of captured fleas into guineapigs. The fleas should be killed by HCN and transmitted to the laboratory in 2 per cent. salt solution. DEVIGNAT (p 969) uses Broquet's medium (calcium carbonate 2, glycerin 20 distilled water 80) for clearing fleas for examination. This prevents putrefaction but ensures the survival of the bacilli up to six days so that they may be isolated for bacteriological examination.

MURDOCK (p. 969) records an outbreak of pneumonic plague in nurses attendants and doctors following the admission of a patient to hospital. Of 16 affected 15 died.

In a child described by FARINAUD (p 970) streptococci and later Gram negative bacilli were found in buboes. Inoculated guineapigs died of acute plague and the streptococci were of low virulence.

Mice which ingested M & B 693 to the amount of about 2 mgm. per gm. weight daily and which were inoculated with 10 000 lethal doses on the 5th or 6th day ingestion of the drug being continued thereafter survived. DURAND (p 970) reported that larger infecting doses often proved fatal but even then the bacilli could not be recovered from the dead animals. Most of the surviving animals showed considerable immunity. SCHÜTZE (p 971) shows that white mice are less resistant to plague than white rats. M & B 693 soluseptasine and sulphone were given before or with the infection to these animals and it was found that M & B 693 was the most successful. Serum prepared against the Otten living vaccine was about equal to M & B 693 in prophylaxis and the author suggests that a combination of these might be better than either alone. GIRARD and GIRARD (p 971) found M & B 693 to be as efficacious as plague serum in the treatment of infected mice and guineapigs.

BHARGAVA (p 971) gives advice on the protection of coolie workers in an anti plague campaign. JAMES (p 972) considers that the vigorous measures taken prevented an outbreak in the Mawchi mines in India.

BABENUSHEV *et al* (p 972) show that fumigation of the burrows of ground squirrels with chloropicrin or calcium cyanide though not entirely eradicating the fleas in the burrows reduces their numbers. TIFLOV and POTAPOV (p 973) found that the majority of all species of rodent fleas in Russia migrate from burrows of field rodents when these are abandoned. TROTIER (p 973) remarks on the successful use of poison bait and other anti rat measures in Hawaii.

The Eastern Bureau of the Health Organisation of the League of Nations (p 973) reports that in India plague has steadily declined in the last 10 years. The same is true of the Dutch East Indies where the decline has coincided with mass inoculation by Otten's living avirulent vaccine. To be successful, fumigation should be repeated every 3 months. ROSIER (p 974) attributes the decline of plague in Java, of which he gives figures firstly to the use of the living vaccine of Otten of which over 6 million inoculations have been given since 1935 and secondly to the campaign of house improvement. SCHÜTZE (p 974) reports on field trials of vaccines in Java. With heat-killed vaccine no superiority of virulent strains over avirulent, or of smooth over rough was seen but for maximal protection of rats it is essential that the vaccine be grown at 37°C. at which temperature envelope antigen production is highest. In mice however envelope antigen is not so important. The superiority of smooth avirulent living vaccine depends on the capacity for survival in the inoculated animal a rough strain is more quickly suppressed.

VOGEL and RIOU (p. 975) show that in Madagascar the incidence of plague has markedly decreased in 1936-1937 compared with previous years. During 1937 vaccination with the living EV vaccine was performed on 77.5 per cent. of the population of 1,051,395 and the authors attribute the decline of the disease to the use of this vaccine. AKCHEZAR (p. 976) gives the characteristics of the EV strain of *P. pestis*.

SOKHEY (p. 976) gives the desiderata for the preparation of vaccines of killed plague bacilli and quotes an experiment in which treatment with antip plague serum gave promising results. The composition of the rat population of Bombay is changing. *R. rattus* and *R. norvegicus* are now highly resistant to plague, but *Gomomys varis* is increasing and is highly susceptible. He gives the growth requirements of *Pest. pestis*. He also (p. 977) states the minimum mouse-protection doses of vaccines prepared by different methods and at different temperatures.

In Brazil apart from deratization on the usual lines, vaccination with heat killed vaccines has been used. BARRETO (p. 977) reports that the disease has been relatively mild. In plague epidemics SILVETTI (p. 977) shows that vaccination produces an undesirable negative phase and prefers to rely on provision for the sick, segregation, disinfection and deratization. BISTREIN (p. 978) for the preparation of sugar vaccine, autoclaves the sugar at pH 6-8, afterwards neutralizing with sterile alkaline solution. In this way the production of acid is prevented.

BAHR (p. 978) shows that the ratin bacillus has undergone little change in 31 years. Rats which survive ratin ingestion may be killed by means of the squill preparation ratinin, though this is not satisfactory for field mice. C IV

YANG (Y. N.) LANDAUER (E.) KOO (C. K.) & LIN (P. C.) Plague Work in Fukien, China, December 1935 to November 1938.—*Chinese Med. J.* 1939, Jan. Feb., Mar., Apr. & May. Vol. 55 Nos. 1, 2, 3, 4 & 5 pp. 55-73, 162-173, 262-275, 383-390, 479-487. With 24 figs.

In the pandemic of plague which started from Hong Kong in 1894 the neighbouring province of Fukien situated opposite the island of Formosa was soon involved. Its two principal ports, Amoy and Foochow became infected in 1894 and 1901 respectively. The present account relates to plague work during 12 months which was started as a result of a severe outbreak of plague at the end of 1935 in Southern Fukien. It deals in a series of chapters with the organization of the provincial plague prevention bureau, an epidemiological survey, sanitary surveys of endemic plague areas, preventive measures and finally, with a rat and flea survey of Lungyen, a town 100 miles up river and the headquarters of the group of workers.

In early days the plague infection was dispersed by rats and fleas in merchandise from the seaports by river into the interior. As most of the province is mountainous, the bulk of inland trade is confined to the waterways and the seaports provided primary endemic plague foci. Some interesting information has been collected of the history of plague development in certain limited areas. On entering such an area the result of infection was a few sporadic cases or a mild outbreak. More or less severe outbreaks followed in subsequent seasons with or without an interval of from one to three or four years.

After a decade of periodical recurrences of epidemics the outbreaks became milder again and in some places the disease disappeared altogether. But the interepidemic intervals continued to show sporadic cases and these were very important as an index of the prospects of epidemic outbreak. The rat communities on farms are rapidly exterminated in an epizootic and as these farms are separated from one another by almost impossible country the epizootic may die out completely. But on the other hand transmission to another area might be effected human sporadic cases would occur and the stage was then set for appearance of a small epidemic. Even so-called sporadic cases however must really be regarded as true miniature epidemics. Villages likewise may be the source of reinfection of a new and susceptible rat population in the towns. No differences could be observed in the way in which plague attacked human beings in the matter of sex age or occupation. It does not seem to have been possible in the present investigation to obtain actual data of length of the incubation period of plague but from the fact that dead rats were always found 4-6 days prior to the onset of the disease in human cases the incubation period must be within this limit. Pneumonic plague is rightly feared in China but in the present year's epidemic only two cases of secondary pneumonia occurred in two bubonic cases. One of these gave rise to a small pneumonic epidemic of 4 persons in the same house.

A most interesting albeit melancholy account is given of present-day sanitation in many Chinese towns. Water supply is from wells often in a state of disrepair sewers are open channels latrines are of varied types and human faecal matter is much in request for fertilizer garbage disposal is still frequently primitive and streets and housing are not sanitarily satisfactory. It may be said indeed that conditions generally are highly favourable to rat infestation although this must be ascribed very largely to the impoverishment of the people. Certain differences are noted in the architecture of North and South Fukien but over the whole province rat infestation is almost a regular state of affairs.

Preventive measures adopted for the control of plague follow the usual lines. Rat burrows were treated by the calcium cyanide method of fumigation and a house-to-house distribution of poison bait was made by the fumigators. Rat proofing measures for shops took into account the protection of (1) bulk stock (2) replenishment stock and (3) retail goods. Economically this division of rat proofing methods into three classes was a conspicuous success that kept the total costs of the campaign very low. The methods also constituted a welcome insurance for the shopkeeper of protection of his goods against spoilage and consumption by rats. In Lungyen great help was accorded to the work of rat-harbourage elimination and rat proofing by military as well as civil authorities. The staff of the 10th Army assisted in the conducting of several clean-up campaigns each taking nearly a week's work of over one hundred inspectors. Rules governing the construction of new houses were discussed with the local authorities as regards method of enforcement and distributed in pamphlet form to the local building constructors.

A chapter on the rat and flea survey of Lungyen is the last of this series. A total of 2,345 rats trapped during the year was submitted to examination and the species of fleas found were —*X cheopis* L. *musculi* M. *anisus* and *N. nicanus*.

The account of plague work given in these articles shows evidence of excellent organization and very praiseworthy co-operation between all the authorities concerned.

RAO (S Raghavender) Some Observations on Plague in Calcutta.—*Calcutta Med. J.* 1939 Aug Vol 36 No 2, pp 89-105 With 5 figs.

The long-continued absence of epidemic plague from Calcutta is well known but has scarcely been fully studied. Sporadic cases of plague have occurred at infrequent intervals and attract but little attention. It was the occurrence of such a case in a bostee or group of huts which led the author to take up a more intensive investigation of the problem especially as regards the possibility of importation. His work has shown that even in such a very small population as that of a bostee deaths may be occurring which may be plague and that the known factors of rat density, flea infestation, climatic conditions of temperature and humidity in Calcutta are less unfavourable to the development of plague than elsewhere. He found no evidence to support the contention that the case of plague in question was imported and he is led to suggest that plague cases would be found if looked for and that some systematic examination of the rodent population, including the bandicoot as well as the smaller rodents is desirable. Such an examination would naturally take up the question of the relative immunity of the Calcutta rodent population to plague infection.

BOLETIN SANITARIO. Buenos Aires. 1938 Nov Vol. 2, No 11 pp. 802-815 With 5 figs.—Antecedentes epidemiológicos de la peste en los puertos de la República Argentina. [Epidemiological History of the Entry of Plague in the Ports of the Argentina.]—Informe presentado a la X Conferencia Sanitaria Panamericana por el Presidente del D.N. de H. Dr Miguel SURSINI.

It was in 1899 that plague was introduced to South America by a Dutch steamer calling at Montevideo with a cargo of rice from India. From Montevideo the cargo after transference to another steamer was taken to Asuncion in Paraguay and by this time an epizootic of plague had broken out and there were also plague cases. The further progress of plague by river brought it to Rosario and then to Buenos Aires in the Argentine Republic. Spread to the ports of the Argentine generally was then only a matter of time. In these ports the difficulties of conducting an anti-plague campaign of sanitation and deratization are very great. They proceeded on the well-known lines and have led to an extraordinary diminution of rats in the ports which has in some cases reached 70 per cent.

W F H

BOLETIN SANITARIO. Buenos Aires. 1938 Nov Vol. 2, No 11 pp 816-822 With 1 fig.—Peste rural en la República Argentina. [Rural Plague in the Argentina.] Informe presentado a la X Conferencia Sanitaria Panamericana por el Presidente del D.N. de H. Dr Miguel SURSINI (Preparado por los Dres. C. A. ALFARADO y J. M. DE LA BARRERA).

In the Argentine as in other countries the type of plague known as sylvatic has assumed importance because of its tendency to appear in

epizootic form and to spread over a wide extent of country. The epizootic makes its appearance during the winter and fades out in spring. It reappears again the following winter. The infection in animals is of subacute type and death may take place without much in the way of macroscopic lesion. Among the animals affected are *Microcavia australis*, *Galea musteloides*, *Graomys griseoflavus* and to a less extent *Lepus europaeus*, *Hesperomys murillus* and *Sylvilagus brasiliensis*. The parasitic *Siphonaptera* are represented by species of the genera *Parapsyllus*, *Thopalopsyllus* and *Hectopsylla*.

One of the features of sylvatic plague is the small amount of human infection which is experienced. This however is somewhat offset by the tendency to production of pneumonic plague. W F H

CASTELLANI (Aldo) Brief Note on a Culture Medium used in the Differentiation between *B. pestis* (*Pasteurella pestis*) and *B. pseudotuberculosis rodentium* (*Pasteurella pseudotuberculosis rodentium*) — *Jl Trop Med & Hyg* 1939 June 1 Vol. 42, No 11 p 158. With 1 coloured plate [Summary appears also in *Bulletin of Hygiene*]

The author proposes a method for cultural differentiation of *P. pestis* from *P. pseudotuberculosis rodentium* by their action in media containing glycerol and rhamnose. The latter produces acidity in one or both of these whereas the former does not. The composition of the medium used is Rhamnose 1 gm, glycerol 4 cc, litmus solution (Kübel and Tiemann) 5 cc, agar 2 gm, water to 100 cc, pH 7.2.

In this *P. pestis* effects no change in colour unless perhaps to darken the blue whereas ten out of eleven strains of *P. pseudotuberculosis rodentium* changed the colour to red in two days and the remaining strain gave a similar though delayed, reaction. The author states that all strains of the latter do not ferment both, some produce acidity in glycerol but not in rhamnose, some in rhamnose and not in glycerol.

RAO (M. Sadashiva) The Nutritional Requirements of the Plague Bacillus — *Indian Jl Med Res* 1939 July Vol. 27 No 1 pp 75-89 [23 refs.]

Very interesting work has been done in late years on the nutritional requirements of microorganisms. The autotrophic bacteria regarded as on a low level of evolution, can assimilate carbon dioxide whereas the heterotrophic bacteria are dependent on ready elaborated carbon compounds. The most primitive types of bacteria again can assimilate their nitrogen from inorganic sources, at a higher level amino-acids such as tryptophane may be necessary for nutrition and at the highest level of development not only are a series of amino-acids necessary but also certain accessory growth factors or bacterial vitamins are indispensable. Pathogenic bacteria belong mostly to the last class. The present study is directed to determine whether the plague bacillus can be grown in a simple chemically defined medium, what accessory factors are necessary, any nutritional differences between virulent and avirulent strains, what amino-acids are essential as growth factors. The principal findings are — (1) Three amino-acids

proline, phenylalanine and cystine are indispensable while the presence of glycine though not essential, is stimulatory (2) Accessory growth factors have no essential rôle in the nutrition of the plague bacillus. (3) Virulent and avirulent strains show little difference in nutritional requirements. W F H

TUMANSKY (V) Influence de *B. proteus vulgaris* sur le *B. pestis*. [Influence of *Proteus vulgaris* on *Past. pestis*.]—*Rev. Microbiol., Epidemiol. et Parasit.* Saratov 1938. Vol 17 No. 1-2. [In Russian pp 20-27 French summary pp. 27-28.]

Proteus vulgaris is antagonistic to *P. pestis* which finally disappears if the two organisms are cultivated together. This action of the *Proteus* organism is exercised only in living culture. Neither dead cultures nor bouillon culture filtrates possess any such effect. The virulence of the plague bacillus is at the same time diminished. It is understandable how plague bacilli disappear in decomposing human or animal bodies, for the putrefaction is to a considerable extent due to *Proteus* organisms. In a body kept at 25°-30°C the virulence of plague diminishes very rapidly much less rapidly at 12°-15°C. W F H

RUSCO (Carlo) Persistenza di vitalità e virulenza del bacillo della peste nel midollo osseo. [Viability and Virulence of Plague in Bone Marrow]—*Rendiconti Istituto di Sanità Pubblica*, Rome. 1939 Vol 2 Pt 1 pp 197-200

The importance of the examination of the bone marrow in plague rats, especially if long dead, has been abundantly confirmed. In these experiments the author has been able to show how long the plague bacillus may maintain itself alive and virulent in rat or guinea-pig cadavers. He found that this time extended to 8 or 10 months and that after 10 months pure cultures of the plague bacillus, without contamination by the putrefactive *Proteus* organism, could be obtained from the bone marrow of the femur. The vitality and virulence of the plague bacillus moreover had not undergone any modification during this time. Such survival of the plague bacillus permits acari, which live on the bodies of mummified rats to become infected. W F H

BREITINGER (D) Action de la chlorure de chaux sur le bacille pesteux. [Action of Calcium Chloride on the Plague Bacillus].—*Rev. Microbiol. Epidemiol. et Parasit.* Saratov 1938 Vol 17 No 1-2. [In Russian pp 116-119 French summary p 120.]

A 2½ per cent. solution of calcium chloride kills a bouillon culture of plague in 10 minutes. Scraps of cloth infected with a 24-hour culture exposed to the action of a 10 per cent solution are sterilized in 10 minutes. A 20 per cent solution does not kill plague bacilli in sputum after 24 hours action nor in the dead bodies of spermophiles after 36 hours. W F H

SHIMLEY (A) & FEDOROV (A) Disinfectants and the Plague Bacillus.—*Rev. Microbiol. Epidemiol. et Parasit.* Saratov 1939 Vol 17 No 1-2. [In Russian pp 104-111 English summary p 111.]

FAVORISOVA (B) Modifications morphologiques du *B. pestis* sous l'action du bactériophage [Morphological Modifications of the Plague Bacillus by Bacteriophage]—*Rev Microbiol Epidemiol et Parasit* Saratov 1938 Vol 17 No 1-2. [In Russian pp 11-17 French summary pp 17-19 With 35 figs.]

The action of bacteriophage in inactivated human serum and bouillon cultures on virulent *P. pestis* was studied in films prepared every five minutes during the first 12 hours of incubation and then at intervals of 24 48 72, 96 and 121 hours. The atypical forms which made their appearance during 121 hours in the serum culture were describable as rod-shaped round, pyriform semilunar and curved. In bouillon the same transformations took place but so rapidly that at the end of two hours there was nothing to be seen at all in the films.

RUSO (Carlo) La propagazione del bacillo della peste in rapporto alla metamorfosi di insetti coleotteri ed acari [Propagation of the Plague Bacillus in Relation to the Metamorphoses of Coleopterous Insects and Acari]—*Rendiconti Istituto di Sanità Pubblica* Rome. 1939 Vol 2 Pt 1 pp 175-196 [25 refs.]

Flesh eating flies of the genus *Sarcophaga* offer favourable conditions to the multiplication and diffusion of the plague bacillus at all stages of their metamorphosis. The author has found that quite a number of invertebrates, that is to say the ectoparasitic and endoparasitic insects of the morderae and some arthropods can contract plague infection and become true reservoirs of plague bacilli and thus the intermediate sources for the conveyance of infection. IV F H

ROBERTS (J I) Rat and Flea Conditions in a Rural Endemic Plague Area in Kenya.—*Jl Hygiene* 1939 July Vol 39 No 4 pp 355-390 With 4 figs.

Tables give the results in detail of a survey of rats and fleas in the main endemic plague area of Kenya over a further period of two years and graphs deal with rainfall and human plague numbers of *R. rattus* and *X. brasiliensis* index rat plague and human plague for the periods 1934-5 1935-6 and 1936-7. These figures and graphs demonstrate that the factor exercising the greatest influence on the incidence of plague is the *Rattus* population density that the period of maximum incidence of fleas per rat agrees closely with the higher incidence of plague that endemic areas have a much higher *Rattus* density and higher breeding rates than plague-free areas and that the incidence of plague both in man and rats is more closely associated with rat population than any other factor. IV F H

ROBERTS (J I) The Relationship of Field Rodents to Plague in Kenya.—*Jl Hygiene*. 1939 May Vol 39 No 3 pp 334-344

The importance of an increase in the breeding rate and in the mortality rate of field rodents has been greatly stressed of late years in

connexion with the spread of plague epizootics to distant places. This sylvatic plague question is a serious one for public health authorities. In Kenya the matter has been approached essentially from the point of view of proof firstly of the fact and secondly of its importance for human plague. A high mortality among field rodents in the Rift Valley coexistent with an outbreak of disease among sheep was shown not to be plague but what is now known as Rift Valley fever. Bacteriological examination for plague in wild rodents over many years has not shown a single "field rat naturally infected with the disease." During 1930-31 when large numbers of field rats were dying in and around Nairobi a total of 2,750 field rats—*M. coucha*, *Arvicanthus* and *Otomys*—were examined with negative results. In transmission experiments during an outbreak of plague whereas *X. cheopis* and *X. brasiliensis* from rats in huts were easily shown to be vectors experiments with 469 *Ctenophthalmus cabirus* and 816 *Diopsyllus hyssurne* acquired from field rats, in the same area also suffering from an epizootic disease "proved negative.

In the summary to this article one of the conclusions reached for Kenya is that "In the absence of any confirmatory bacteriological evidence to prove that epizootics among field rats are caused by *B. pestis* and the failure to find natural infection among field fleas together with the knowledge of their aversion to feed on man and lack of opportunity to develop such tastes the theories that field rodents and their fleas "are definitely concerned in the spread of plague or in the initiation of outbreaks of plague "appear to be fallacious."

VAN CAMPENHOUT (J) La peste au Congo Belge en 1937 [Plague in the Belgian Congo in 1937]—*Bull. Office Internat. d'Hyg. Publique* 1938, Dec. Vol. 30 No. 12 pp. 2747-2749. With 1 map

The only focus of plague (sylvatic) of the Colony at Lake Albert, produced 6 cases in 1937 of which 3 were bubonic 2 pneumonic and 1 septicaemic. It was found that the rat *Mastomys agardii* is a carrier but *E. rattus rattus* plays no part in the endemic. Of the fleas found on rodents *Xenopsylla cheopis* and *brasiliensis* are in a large majority while *Leptopsylla*, *Diopsyllus*, *Ctenocephalus*, *Sarcopsylla*, *Ctenophthalmus* and *Neopsylla* have also been met with.

LOBANOV (N) & FEDOROV (N) On Pathogenesis of Experimental Plague in Southern Gerbils (*Pallasiomys meridianus* Pall.)—*Rev. Microbiol. Epidemiol. et Parasit. Saratov* 1938 Vol. 17 No. 1-2 [In Russian pp. 57-70 English summary pp. 70-71]

The authors met with a distinct seasonal difference of reaction in gerbils which were experimentally infected with plague. From April to July the type of disease induced was comparatively benign and remained localized. The micro-abscesses produced became encapsulated absorbed and finally replaced by connective tissue, cicatrizing elements. From July to October on the other hand the plague induced was to a large extent acutely septicaemic and generalized.

KOROBKOVA (E) FAVORISSOVA (B) & KRAINOVA (A) Sur la valeur diagnostique des réactions sérologiques dans l'immunité antipesteuse chez les spermophiles [Diagnostic Value of Serum Reactions in Spermophiles].—*Rev Microbiol Epidemiol et Parasit Saratov* 1938. Vol. 17 No 1-2 [In Russian pp 72-86 French summary pp 86-87]

If the serum of spermophils gave retrospectively an agglutination reaction to plague this would be of assistance in marking down a suspected enzootic area especially if this reaction occurred in the older animals and not in the younger. Experiments in the laboratory on 200 spermophils caught in a non plague area showed—(1) The serum of healthy spermophils often agglutinated formalized cultures of the plague bacillus in dilutions between 1-10 and 1-40 (2) Immunization of spermophils with 3 injections of weakly virulent living plague on 3 successive days resulted in production of a feebly agglutinating serum (1-10 to 1-50) by the second week and disappearance of the agglutination after 25 days (3) Spermophils immunized with living bacilli are protected against a very severe test dosage (4) Specific agglutinins appear in the serum only after numerous injections of living bacilli but a single injection is sufficient to confer immunity.

The conclusion drawn is that agglutination reactions are not likely to prove of much value in determining the epidemiology of a district

GIBBONS (R J) Survey of Rocky Mountain Spotted Fever and Sylvatic Plague in Western Canada during 1938.—*Canadian Public Health Jl* 1939 Apr Vol. 30 No 4 pp 184-187

A co-operative survey has been undertaken for the determination of the existence and the danger of occurrence of the two diseases Rocky Mountain spotted fever and wild rodent or sylvatic plague in the Canadian provinces of Alberta and British Columbia. No plague infection was found in the 3 669 wild rodents and 7,582 rodent fleas examined. That is matter of congratulation but does not imply that there should be any relaxation of vigilance as the history of the progress of the infection northward and eastward through the western section of the United States makes probable its extension to Western Canada within the next few years.

Investigation of the reports of Rocky Mountain spotted fever revealed that though the first case had only been notified from Alberta in 1935 and from British Columbia in 1936 fully authenticated cases had occurred as early as 1923 in Alberta and 1917 in British Columbia. Laboratory examination of specimens of the ticks *Dermacentor andersoni* and *D. variabilis* for *Rickettsia dermatitoxenus* were negative although the ticks had been collected in large numbers in the immediate vicinity where cases had occurred. In the course of these examinations several specimens were found to be infected with virulent strains of *P. tularensis* [sic]

ROUDABUSH (Robert L.) Survival of the Tropical Rat Flea in United States.—*Science* 1939 Jan. 27 Vol. 89 No. 2300 pp 79-80

JELLISON (William L.) *Sylvatic Plague Studies of Predatory and Scavenger Birds in Relation to its Epidemiology*—*Public Health Rep* 1899 May 12. Vol 54 No 19 pp. 792-798.

It seems quite possible that flesh-eating birds, especially those depending on rodents "as an important source of food supply might be an important factor in the spread of plague. Again, birds might be agents of transportation to a distance of plague infected fleas. The booby owl for example is a constant companion of the ground squirrel occupying the same burrows with him. The field and laboratory observations reported here were made in a plague epizootic area. Predatory species of birds were found to transport flea-infested rodents and to serve as accidental hosts of rodent fleas. Experimentally, casts from predatory birds fed plague-infected guinea-pig tissue were consistently infectious. In general no very positive conclusion seems to have emerged from these studies.

ESKEY (C. R.) & HAAS (V. H.) *Plague in the Western Part of the United States. Infection in Rodents, Experimental Transmission by Fleas, and Inoculation Tests for Infection*—*Public Health Rep* 1899 Aug 11 Vol 54 No 32 pp 1467-1481

Ground squirrel (*Citellus beecheyi*) infection was discovered within 10 years of the occurrence of plague (1900) at San Francisco in nine Californian counties. In 1834 epizootics occurred in the Sierra Nevada mountainous area since which time systematic investigation has resulted "in the discovery of foci of wild rodent plague in 9 of the far western States exclusive of California. So far it has not been found in the great plains area east of the Rocky Mountains. The absence of domestic rats in most of this affected territory accounts for the absence of epidemics. More than 50 different species of fleas have been found on the western rodents, ground squirrels with an average of 20 per animal and marmots with over 10 fleas each. Nor does the number found on the animal represent the total, for fleas also occupy the nests of rodents. It is not probable that this applies for very long, however to the abandoned nest. In testing experimentally with fleas for the degree of infectiousness of plague infected guinea-pigs, this was found to bear a close relationship to the degree of bacteraemia present. Thus no flea was found to be infected by blood which did not give a culture of *P. pestis*. There did not seem to be much difference between wild rodent fleas and domestic rat fleas in the readiness with which they became infected. Once the flea was proved infected by transmission its average length of life was only 3.2 days, a figure which held good for fleas of different species, but a certain period must elapse for the extrinsic incubation before the bites were infectious." That period varied from 5 to as long as 130 days thus demonstrating that fleas may harbour virulent plague in the gastrointestinal tract for a long time, a fact which is of the highest importance in determining their efficiency as vectors."

The determination of the existence of plague infection in the wild rodents of a territory has now become a regular epidemiological procedure. Inoculation of guinea-pigs with the bodies of captured fleas has been found to be a much more effective means of finding rodent plague infection than by systematic examination of the killed animals themselves. An important discovery was that the parasites

killed with hydrocyanic gas were much more infective than if killed with chloroform or ether due to attenuation of the plague organism brought about by the latter. Thus cyanide gas became substituted for chloroform in killing the parasites before removing them from their hosts. A 2 per cent. salt solution is used in which to transmit the fleas to the testing laboratory. It inhibits the growth of secondary bacteria prevents putrefaction and has no deleterious action on *P. pestis*. If a specimen contains a great many fleas they are usually divided into lots of 50 for inoculation. W F H

DEVIGNAT (R) L'utilisation du milieu de Broquet pour la recherche de la peste des puces. [Broquet's Medium for Examination of Plague Fleas.]-*Ann Soc Belge de Méd Trop* 1938 June 30 Vol. 18. No 2. pp 215-219

Originally suspected fleas were placed in 60° alcohol which is excellent but costly then 10 per cent. phenol and finally pure phenol which had the advantage of clearing the fleas for examination were used. All these media however destroyed organisms so that although usable for identification of flea species no bacteriological examination of the fleas could be made. Broquet's medium with the composition calcium carbonate 2 glycerin 20 and distilled water 80 acts as clearing agent for fleas ensures a survival of plague bacilli for several days and prevents putrefaction. In the village which is undergoing its monthly deratization the fleas recovered from the killed rats are placed in Broquet's medium a medical orderly cuts off the legs of the rats with a pair of scissors while another obtains femoral bone marrow with a syringe and emulsifies it in a small flask containing 5 cc. of sterile normal salt solution. Lastly a guineapig is inoculated subcutaneously with 1 cc. of the emulsion. If now on arrival at the laboratory of the district the guineapig dies of plague it remains possible to isolate a strain of plague from the fleas which have been collected from the same place on the same day and from the same rats.

All were cases of pneumonia and only one nursing sister survived. A diagnosis was made by exhumation of one of the fatal cases removal

attendant upon his work. The dangers are of course, from fleas and from the poison gas of disinfection. It is recommended that his clothing should be white and so disposed that fleas can get no access to the skin anywhere while he should wear a glove of thick rubber reaching from fingers to elbow as protection during cyanogassing. Coolies should work in batches of two so that one can keep a watch on the other for fleas. It is important likewise that hours of work should not be too long nor too continuous lest the workers become careless and off their guard against infected fleas.

A note to this article gives as simpler methods (a) protection of workers by inoculation with antiplague vaccine (b) wearing of white overalls and (c) smearing of the hands up to elbows and legs up to knee with kerosene-soap emulsion daily just before starting the work. If cyanogassing is done with calcid briquettes it carries little danger to either worker or public

JAMES (E. R.) The Incidence of Plague in Mawohi Mines and the Advantage of adopting Early Preventive and Prophylactic Measures. —*Indian Med Gaz* 1939 June. Vol 74 No 6. pp 347-348

Plague was prevalent from December to the following February in the area for the first time. As the area was densely populated, rats fairly numerous and the camps overcrowded, it might have been expected that an epidemic, if it occurred, would be severe. The non-occurrence of such an epidemic may be reasonably ascribed to the vigorous anti plague measures adopted. Only five cases of plague did occur

BAKHUISHEV (V. P.) & others Observations on the Fate of Fleas dwelling in the Nests of Ground Squirrels situated in the Regions that had been subjected to Entire Poisoning—*Rev Microbiol Epidemiol et Parasit* Saratov 1937 Vol 16 No 3-4 pp 467-474 [In Russian] English summary [Summarized in *Rev Applied Entom* Ser B 1939 Aug Vol. 27 Pt. 8. pp 170-171]

An account is given of investigations in 1935 and 1936 in 8 districts of the province of Ordzhonikidze (northern Caucasus) to determine whether fumigation of the burrows of ground squirrels [*Citellus pygmaeus*] with chloropacrin or calcium cyanide also destroys the fleas in them. The work was done in spring in localities in which all the burrows had been fumigated for two or three consecutive years to ascertain the presence of fleas, the entrances of the burrows were opened and wads of cotton-wool were inserted into them and examined 24 hours later. Fleas occurred on 44 wads out of 4 474 inserted in the morning (0.9 per cent) and on 20 wads out of 3,182 inserted in the evening (0.62 per cent). It was shown, however by examining nests from treated and untreated burrows that the numbers of fleas were reduced by fumigation. The average numbers per nest were 15.7 in fumigated burrows that still retained the straw plug and were covered with earth, 31.3 in fumigated burrows that had been opened for some time and may have been used by various small animals, and 49 in the untreated inhabited burrows.

Fleas collected from the ground squirrels belonged to 14 different species, the abundance and local distribution of which are shown in a table. They included *Ceratophyllus (Oropsylla) slovakii* Wagn and Ioff, which had not previously been recorded from the northern Caucasus.

- TIFLOV (V E) & POTAPOV (V D) Migrations of Fleas of Ground Squirrels *Citellus pygmaeus* Pall.—*Rev Microbiol Epidemiol et Parasit* Saratov 1937 Vol 16 No 3-4 pp 438-466 With 1 graph & 2 figs [14 refs] [In Russian] English summary [Summarized in *Act Applied Entom* Ser B 1939 Aug Vol. 27 Pt 8 p 170]

In view of the importance in the Russian Union of fleas of rodents in the dissemination of plague and to supplement investigations by other workers field observations on the migration of fleas from abandoned burrows of *Citellus pygmaeus* and on their survival under natural conditions were carried out in Western Kazakhstan from 1st August to 1st December 1934 and from 4th March to 15th November 1935. For this purpose all the ground squirrels over an area of 25 acres were caught and the fleas that tried to leave 50 burrows were trapped. The traps consisted of a metal box containing water which the fleas entered through a tube the end of the tube was inserted into the entrance hole of the burrow. The results which are tabulated showed that all the species of fleas that occur on ground squirrels migrate from abandoned burrows. Species that have well developed eyes and infest the host itself (*Ceratophyllus tesquorum* Wagn and *Frontopsylla semura* Wagn and Ioff) markedly predominated whereas those that have rudimentary eyes and inhabit the nests (*Aecopsylla setosa* Wagn. and *Ctenophthalmus pollex* Wagn and Ioff) were comparatively scarce. In 1934 most of the fleas migrated in August and only two in November. In 1935 the maximum number of fleas was caught in April after which there was a sharp reduction and only one flea was taken in July. After migration had ceased in July 32 burrows were opened and examined for the presence of fleas. 19 live individuals were found, in 7 burrows. A few rodent fleas were caught outside burrows in 1935 and observations on batches of *N. setosa* showed that many could survive on the soil for 24 hours and a few for 48 hours or more.

HAWAII TERRITORY OF ANNUAL REPORT OF THE BOARD OF HEALTH FOR THE FISCAL YEAR ENDED JUNE 30 1938 (TROTTER (F E) Territorial Commissioner of Public Health) [Plague pp 182-205 With 9 graphs.]

Under the heading Plague this report includes a number of subsidiary reports of administrative type from the health officers sanitary engineers and trappers of the plague service. A very interesting observation is made by the Territorial Commissioner of Public Health. The principal advance made in plague control measures during the year was the discovery on the Island of Hawaii that the rat population could be reduced markedly by the proper application of a poison bait. The standard bait consisted of a piece of banana loaded with phosphorus. Other measures of limited application were the use of (1) calcium cyanide dust (2) carbon bisulphide for exposed burrows and (3) sodium arsenite solution for spraying.

ANCHEZAR (B.) La infección experimental determinada por la Cepa EV de Girard (= *Pasteurella pestis* avirulenta) Su estudio bacteriológico y anatómo-patológico [Bacteriological and Pathological Study of the EV Plague Avirulent Strain.]—*Folia Biol* Buenos Aires 1938 Sept-Oct-Nov-Dec. Nos 90-91-92-93 pp 393-396

Experiments conducted with the EV strain of GIRARD showed that (1) this strain, originally isolated from a case of bubonic plague, corresponded to *P. pestis* in all respects (2) It was avirulent for laboratory animals (3) The inoculation of large doses killed animals by toxæmia (4) The strain had a marked selectiveness for lymph nodes and spleen appeared for a short time in the blood and bone marrow and remained for longer time at the site of inoculation (See also this Bulletin 1939 Vol 36 p 313) W F H

BOMBAY REPORT OF THE HARTKEE INSTITUTE FOR THE YEAR 1937 DORNEY (S S) Director (Plague pp. 29-40 47-48.)

Much of the research work noticed in this report has, naturally already been published in journal form. The Director reviews the main points which have emerged from these researches. Plague vaccines made from broth cultures are more potent when incubated at 27°C than at 37°C but the reverse holds good for agar cultures. Those vaccines which are killed by the application of heat for 15 minutes at 55°C are better than those where phenol or formalin are used. Special interest centres round the testing of the relative values of killed virulent plague vaccines and the same strain used in the avirulent but living state in view of the extensive use of living plague vaccine in other parts of the world. It has been found, however that the living avirulent strains tried have varied greatly in antigenic value from one of high protective value to one devoid of protective power. No measurable differences on the other hand, have been found in the antigenic value of a large number of virulent strains. In a small trial of anti-plague serum in which 124 cases were treated, 69 with serum and 55 controls with intravenous iodine the controls exhibited a mortality of 65 per cent compared with only 27 per cent of the serum-treated.

Continuous observation has been going on for a very long time now in Bombay of the composition of the rodent population. It has been found that this population is changing. When plague was raging in 1907 the rodents responsible for the spread of plague in the city were *Rattus rattus* and *Rattus norvegicus* which formed over 99 per cent. of the population. In 1937 these two species together form only about 70 per cent. and *Gnawomys varius* makes up the remaining 30 per cent. *Gnawomys varius* moreover is highly susceptible to plague infection while the other two species are now highly resistant.

Some biochemical studies on the growth conditions of the plague bacillus have shown that its nutritional requirements are relatively simple and "it shows no dependence on accessory factors for growth." Three strains were used a mixture of 8 amino-acids supplemented with phosphate buffer sodium citrate and magnesium sulphate was experimented with to see which of the amino-acids was indispensable to growth. Proline and phenylalanine were wholly indispensable.

In the absence of cystine only one strain grew. Glycine was nearly but not quite essential for two strains while alanine appeared to be so for one strain.

BOMBAY REPORT OF THE HAFSINE INSTITUTE FOR THE YEAR 1938
[SOLHEY (S S) Director] [Plague pp 30-41 51-52]

The work carried out during the year on plague is very much on the lines of the previous report for 1937 (above). Perhaps the most interesting investigations are those on standardization and relative value of differently prepared vaccines. The method of statistical assessment of the results used is that for estimating fifty per cent. end points employed by REED and MUEVICH (*Amer J Hyg* 1938 Vol 27 p 493). Thus for example in minimum mouse-protective doses (1) Broth vaccine incubated at 27°C protected with 0.0025 cc. at 37°C with 0.008 cc. (2) agar vaccine incubated at 27°C with 0.0851 cc. and at 37°C with 0.0017 cc. (3) live avirulent broth vaccine at 27°C with 0.0025 cc. and at 37°C with 0.008 cc. (4) live avirulent agar vaccine at 27°C with 0.0085 cc. and at 37°C. with 0.0017 cc. The effect of the mode of killing was also carefully estimated.

BARRETO (João de Barros) A peste no Brasil nos ultimos 5 anos.
[Plague in Brazil in the Last Five Years]—*Arquivos de Hig*
Rio de Janeiro 1938. Nov Vol. 8. No 2 pp 347-374

Plague has been endemic in Brazil especially in the North East. The people of this region are chiefly occupied with the cultivation of corn, cotton and manioc. In the factories there are plentiful supplies of food for rats and the conditions are conducive to the propagation of fleas. During the period of the quinquennium 1934-1938 there were 1,393 cases of plague—208 in 1934 822 in 1935 314 in 1936 35 in 1937 and 14 up to August 1938. It was a relatively benign type of plague with mortalities of 35 per cent. in 1935 39.5 per cent. in 1936 43 per cent. in 1937 and 46 per cent. in 1938. This compares favourably with the ordinary mortality of 60 to 95 per cent. which attaches to bubonic plague. The rats involved were of domestic type—*norvegicus* *rattus* and *musculus*—while the fleas were of the species *X. cheopis* and *brasilensis*. An active campaign has been pursued against the disease and doctors and other workers have been put through a rapid special course before being detailed for the work. Methods of deratization and immunization have been of the usual description. The vaccines used were killed vaccines (1) 2 cc. of a culture suspension from glycerin agar heated 1 hour at 65°C. and (2) a growth at room temperature of 48 hours on agar of pH 7.4 where the suspension was treated with formalin to give a final concentration of 1:2,000 and heated 1 hour at 50°C. For inoculation purposes a dilution was made to 1,000 million organisms per cc. and 2 inoculations were given at 7 days interval.

SILVETTI (Luis M.) Informe sobre una epidemia producida en Santa Ana (Tucumán) denunciada como peste septicaemica. [An Epidemic of Septicaemia Plague in Santa Ana (Tucuman) Argentine.].—*Boi Sanitario* Buenos Aires. 1939 Mar Vol. 3 No 3 pp 131-140

The description given is of an epidemic which on bacteriological report was regarded as plague. The author attempted by exhumation

severely but he thinks that in the natives there is a special resistance of the cutaneous vascular system. Full serological investigation was not possible. In the treatment of typhus in Abyssinia, GIUNTA and D'ICCAZIO (p. 988) give intravenous mercurochrome with ascorbic acid and vitamin B₁, glucose and cardiac stimulants.

THOMPSON (p. 990) describes an outbreak of (probably) louse-borne typhus in a member of the Viceregal bodyguard in India and in contacts. The first infection appears to have been contracted in Kashmir. CLEAVE (p. 990) reports a case positive to *Proteus* OX19 whose infection was contracted in Shanghai.

JORDAN and FLETCHER (p. 990) find that an *impero* cresylic product is lethal to lice if ammonia is added.

DYER (p. 991) shows that there has been a considerable increase in the numbers of cases and distribution of endemic typhus reported in the United States in recent years. Practically all the small rodents examined are susceptible. KEMP (p. 991) shows that in Texas endemic typhus is usually contracted at places of work or in rat infested houses. He considers it to be distinct from Brill's disease which Zinsser has shown to be caused by the classical virus.

LORANDO and PAPANASTASSIOU (p. 991) quote two patients, mother and son, with endemic typhus. The rash in the son was profuse but none occurred in the mother. LORANDO (p. 992) reports double orchitis in a case of endemic typhus. BRUNEAU (p. 992) describes a case of endemic typhus.

ZIA *et al* (p. 992) describe the techniques for culture and staining of murine Rickettsia which were successful in experiments on 42 animals. ASHGSTED and LAWKOWICZ (p. 993) cultivated 8 strains of murine virus from infected rats. Six of these were Rickettsial in appearance and serological properties, the other two were more like *Proteus*. Living and formal-killed Rickettsia produced immunity to murine typhus virus.

Murine typhus virus injected into the peritoneum of white mice produces paralysis and LARGET and DURAND (p. 993) compare it with the neurotropic virus of yellow fever. BRUNEAU (p. 993) found that murine typhus virus did not produce fever when injected into Tonkinese patients suffering from nervous diseases. He concludes that many cases in the natives pass undetected.

VIOLLE (p. 994) succeeded in infecting rats by allowing them to feed on material contaminated with urine from infected rats and human patients.

GROUD and PANTHIER (p. 994) show how the virus of murine typhus gains in virulence for white mice on passage through these animals.

RUIZ CASTAÑEDA (p. 994) describes a mild form of typhus, probably murine endemic in Zacualco. *Proteus* X19 was agglutinated in one case.

IWATA (p. 995) classes the strains found in Manchoukoo as murine intermediate and epidemic and shows how the clinical features correspond with the biological characters.

LÉPINE (p. 995) and FERNANDEZ (p. 996) describe clinical cases of splins.

Tick-borne.—GEAR (p. 996) finds that in South Africa the agglutination of *Proteus* OX19 rises to high titre in louse-borne typhus, that of OXA is irregular. The disease is therefore in the same group as classical European typhus. In guinea-pigs orchitis is rare. He recognizes two forms of tick typhus, one mild with constant primary

sore and contracted from veldt ticks the other severe with occasional lache noire and contracted from dog ticks. In serological reactions morphology and distribution of the Rickettsia South African tick typhus resembles Rocky Mountain and boutonneuse fever. He (p 997) considers that the severe type of tick typhus occurs in older people and is transmitted by adult *Haemaphysalis leachi* from domestic dogs in towns.

Blood from a case of spotted fever reported by FITZPATRICK (p 998) produced fever and orchitis in guineapigs which were later found to be immune to a virulent Rocky Mountain fever strain.

BAUERSFELD (p 998) reports an unusual and fatal case of Rocky Mountain fever apparently contracted in Florida. PHILIP and DIAS (p 998) were unable to transmit the virus of Rocky Mountain fever through various Reduviid bugs.

DE MAGALHÃES (p 998) found the virus of Muías Geraes fever in rabbits opossums ticks and bed bugs. The virus passes through the placenta of Rhesus monkeys but not through shaved skin. It rarely passes an LS filter candle but is cultivable on the chorio-allantoid membrane of fowl embryo.

DE MAGALHÃES (p 999) notes that although clinical diagnosis is enough in typical cases of Muías Geraes fever in mild cases further means must be employed.

Mite-borne.—BRUNEAU and CHAPUIS (p 999) describe a case positive to *Proteus OXA* blood inoculated into the eye of a rabbit gave indocyclitis with keratitis and continued fever the typical tsutsuga mushi reaction.

GLYNNER and SCHROEDER (p 1000) show that 46 Europeans have been infected with the *Proteus OXA* type of fever in a district of New Guinea since 1934. The bush is heavily infested with mites. WIJERAMA (p 1000) reports two cases of *Proteus OXA* type of fever in Ceylon. In the Pescadores KAWAMURA and YAMAMOTO (p 1000) show that 32 cases of *Proteus OXA* type of fever have been investigated.

Vaccination.—In the troops in Morocco LAURENS *et al* (p 1000) found that cases of typhus occurred even among the vaccinated and believe this to be due to the fact that the virulence of the vaccine cannot be maintained constant and that if kept too long it loses its efficiency. They suggest the use of dried excreta of fleas.

GAUD (p 1001) reports satisfactory results from widespread vaccination by the method of Blanc during an epidemic in Morocco. MARIANI (p 1001) shows that in 13 000 vaccinations by the method of Weigl in Ethiopia only a few persons showed severe reactions. A few cases of typhus were seen in the vaccinated but these were usually mild.

ZINSSER *et al* (p 1002) found that animals vaccinated with phenol or formal killed agar culture of Rickettsia were immune to test doses. VEINTENILLAS (p 1002) used Zinsser's formal vaccine and found that it protected human volunteers against infection with 2 000 minimum infective doses. One dose of the vaccine protected against murine virus but 3 or 4 doses did so against classical virus also. It is proposed to use this vaccine on a large scale in Bolivia.

SARKAR (S K) A Case of Typhus Fever.—*Indian Med Ga.* 1939
Apr Vol. 74 No 4 pp 223-224

A case of fever in a European in which the Widal reaction was negative but the Weil-Felix was positive for *Proteus OX2* with a

no effect in typhus. That the condition is due to typhus virus can be proved by a study of the temperature chart immunity and agglutination tests. The older and heavier guineapigs give the most marked reaction which varies according to the resistance of the animal and the origin of the virus—blood, brain, etc. The scrotal reaction may appear whatever the source of the virus, but is most common with that of murine typhus and occurs only rarely with that of historic typhus.

NICOLLE (P) & SIMONS (H) Accélération de la sédimentation des hématies dans le typhus murin expérimental du cobaye. [Acceleration of the Sedimentation of the Red Blood Cells in Experimental Typhus in the Guinea-pig.]—*Bull Soc Path. Exot* 1938 Dec 14 Vol 31 No 10 pp 837-846. With 2 graphs

Fifty guineapigs were infected and the reaction tested and compared with 90 control animals.

Conclusions.—In experimental typhus the acceleration of the rate of sedimentation of the red cells is considerable. It commences early in the illness and reaches its maximum on the 8th day, decreases rapidly from the 9th to the 12th and more slowly from 13th to 24th day. Two months after infection it disappears completely. When animals which have recovered are remuculated with the virus acceleration does not occur again.

It is necessary to exclude bacterial infections as these may also produce the same effects.

LESTOQUARD (F) Lode dans la coloration des Rickettsia. [Iodine in the Staining of Rickettsia.]—*Bull Soc Path. Exot* 1939 May 10 Vol 32 No 5 pp 466-467

This method was first suggested in 1926. Films are fixed in iodized alcohol 98 parts alcohol, 2 parts iodine, for 8 to 10 minutes. Wash in pure alcohol to remove the iodine, then stain with Giemsa's stain. This method has been used by the author in his work on *Rickettsia canis*.

D H

GIROUD (P) & PANTHIER (R) La réaction au lugol sur les cellules parasitées par les rickettsies. [The Reaction to Lugol of Cells containing Rickettsia.]—*Bull Soc Path. Exot* 1939 Jan 11 Vol 32 No 1 pp 14-17

This reaction has been described in trachoma, and the authors tried out the same technique using films made from infected tissues of guineapigs. The Mooser cells in the films did not give any reaction. Some cells gave reactions but these did not contain Rickettsia. It is suggested that the reaction is due to staining of glycogen in the cells by lugol. [Presumably this refers to Lugol's solution.]

D H

COX (Herald R) Use of Yolk Sac of Developing Chick Embryo as Medium for Growing Rickettsias of Rocky Mountain Spotted Fever and Typhus Groups.—*Public Health Rep* 1938 Dec. 23 Vol 53 No 51 pp 2241-2247

Inoculation was made into the embryonic membrane enclosing the yolk mass.

The inoculum was

Rocky Mountain fever virus
Endemic typhus virus
Boutonneuse fever virus
Brazilian spotted fever virus
European typhus

blood of guineapig
testicular washings
blood of guineapig

It was found possible to pass all these viruses in series from egg to egg in many instances the embryo was killed by the infection by the 3rd or 4th day. It was also found that the virulence of the inoculum for guineapigs was increased by passage in this manner. It was from 100 to 1 000 times more infective than the same virus from mammalian tissues and was comparable to the virulence in the tissues of the tick.

FIGOURY (L.) & BERNARD (M.) Existence de *Rickettsia canis* dans le Proche-Orient [Existence of *Rickettsia canis* in the Near East.]—*Bull Soc Path Exot* 1939 Jan 11 Vol 32. No 1 p 19

A number of sick dogs were examined films made from lung puncture were stained but no *R canis* were noted. Forty-six dogs from the local pound were examined similarly and in one 6 months old numerous *Rickettsia* were noted in the mononuclear cells in a film from a lung puncture.

The stained film was sent to MM DONATIKY and LESTOQUARD and they definitely diagnosed the parasite as *R canis*.

This is the first time this parasite has been noted in the Eastern Mediterranean (Beirut)

HERZIG (Anna) Eine neue *Rickettsia* Spezies der Laus, der Erreger einer spontan aufgetretenen epidemischen Erkrankung des Menschen [A New Species of *Rickettsia* of the Louse the Cause of a Spontaneous Epidemic of Fever in Man.]—*Zent f Bakt* I Abt Orig 1939 Mar 30 Vol 143 No 5/6 pp 299-302.

Forty to fifty people in Weigl's laboratory feed voluntarily the normal lice which are bred in large numbers for purposes of preparing anti-typhus vaccine. Approximately 300 000 lice are fed daily.

In April 1938, two of these men developed fever with pains in head and back the fever only lasted 2 or 3 days but was followed by relapse. Later the greater number of the men became ill with the same symptoms and a large percentage of the lice showed *Rickettsia* infection. These organisms were extracellular and resembled *R pediculi*. *Rickettsia* could be seen in the blood of the patients in large numbers. It was possible to reproduce the disease in volunteers by injecting subcutaneously the gut contents of infected lice and also by feeding lice on normal men. The incubation period was about 3 days. The *Rickettsia* can be passaged from louse to louse but soon loses its pathogenicity for man. No infection could be produced in any of the usual experimental animals.

All the characters of this *Rickettsia* remind one of *R weigli* and also of *R quintana* the cause of trench fever. Further experiment will be necessary to decide whether these three *Rickettsia* types are actually one and the same or are only morphologically similar.

The author is inclined to the view that these types are distinct from one another and differ just as do different strains and types of dysentery bacilli which produce different types of clinical dysentery

D H

WERNER (H.) *Neuere Ergebnisse der Fünftagesfieberforschung* [Recent Investigations on Five Day Fever]—*Deut Med Woch* 1939 Feb. 3. Vol 65 No. 5 pp 174-176.

During the years of the Great War there were large epidemics of trench fever also many cases of the disease were missed and classified as simple continued fever slight rheumatism or influenza

At the end of the war the disease disappeared as suddenly as it had come For this reason it was not possible to carry out research on any large scale since the war Yet the disease has been reported from time to time in Poland, Galicia and in Japan In 1938 Professor WEIGL wrote to the author and stated that in 1934 there were 18 cases of clinically typical trench fever among the personnel in his laboratory About 40 persons were used to feed the stock lice and 18 of them developed the fever and the Rickettsia found in the lice were similar to *R. quintana*.

The symptoms of the patients corresponded with those of trench fever seen during the Great War All these people had been previously vaccinated with Weigl anti-typhus vaccine

Inoculation of clean lice was successful and the Rickettsia in the lice were extracellular normal people were infected from these lice. The author refers to the work of OGATA in Japan where cases of five day fever have occurred from time to time and this observer has succeeded in isolating the virus from the blood of patients by intra-testicular inoculation in rabbits—pure cultures have been thus obtained and the disease has been produced in man by inoculation of these cultures In 1927 Werner suggested the use of the virus of trench fever in the treatment of neurosyphilis and it has been so used recently by Ogata in Japan.

D H

DYER (R. E.) Similarity of Australian "Q" Fever and a Disease caused by an Infectious Agent Isolated from Ticks in Montana.—*Public Health Rep* 1939 July 7 Vol. 54 No. 27 pp 1229-1237 With 6 figs. [12 refs.] [Summary appears also in *Bulletin of Hygiene*]

In 1935 DAVIS and COX obtained from *Dermacentor andersoni* a virus (V.) which would pass through Berkefeld N and W filters, which held back bacteria and the viruses of typhus and Rocky Mountain spotted fever The virus survives in and is transmissible by the *Dermacentor* in nymphal and adult stages, if ingested in the larval stage and it survives through the eggs to the larva. It does not produce agglutinins for *Proteus* V strains, nor did it infect *M. musculus*. In guinea pigs it produces fever for 2-8 days after an incubation of 4-6 days there is no scrotal reaction Guinea pigs recovered from Q fever virus were found immune to the new virus of Davis and Cox. *Rickettsia burneti* is found in spleens of mice infected with Q fever

and workers in Australia have found *M. rhesus* guineapigs white mice several native rodents the bandicoot (*Isodon macrourus*) susceptible. In guineapigs *Q* virus produces a febrile reaction for 4-6 days after an incubation ranging between 2 and 18 days again there is no scrotal reaction.

As stated above guineapigs recovered from *A* fever were immune to inoculation with λ virus. Other cross immunity tests were carried out with two strains of typhus fever one endemic and one epidemic with two of Rocky Mountain spotted fever one avirulent strain from Montana and a milder one from Maryland. Figures in the text show that there is no cross immunity between the λ strain and the typhus and spotted fever strains nor between the *A* fever and spotted fever strains but as stated above there is complete cross immunity between λ and *Q* fever strains. Other figures demonstrate the results of agglutination and protection tests with the different sera. Briefly as regards the subject of this article definite protection against λ virus was given by λ serum and *Q* fever serum but none by spotted fever serum. The author sums up the points of similarity and difference as follows —

Epidemiology — *Q* fever has been recognized principally in persons associated with animals which suggests infection from direct contact with infected animal tissues or with animal parasites.

The epidemiology of the Montana infection is unknown but the presence of the virus in ticks suggests that human infections may be found in rural areas.

Clinical — The one recognized human infection with the Montana virus was very similar to the published descriptions of the Australian *Q* fever cases.

Susceptibility of animals — As far as work has been carried out the only point of difference in susceptibility of animals to the two infections is the failure of the American workers to find the monkey susceptible in contrast to the success in infecting this animal in Australia.

Serology in man and animals — Neither disease has been found to produce agglutinins for Proteus λ strains. It should not be forgotten that the opportunity to study this point in human beings in this country has been limited to one case (an accidental infection of a laboratory worker in Montana).

Reactions in guinea pigs — The clinical pictures in guinea pigs, as described in the literature are similar with the exception that the Montana infection has been reported to produce a definite local skin reaction following subcutaneous inoculation while the Australian workers state that no particular local reaction follows subcutaneous inoculation. A comparison of the two strains in this laboratory shows that the *Q* fever strain produces general reactions in guinea pigs which although similar to those produced by the Montana virus are milder. This fact may be explained by the attenuation of the *Q* virus during transit to this country. Rickettsiae have not been observed in guinea pigs with *Q* fever while they are present in abundance in guinea pigs infected with the Montana virus.

Cross immunity tests — These tests are identical, with the exception that epidemic typhus, and, to a lesser extent endemic typhus apparently produce more immunity to *Q* fever than to the Montana virus.

Agglutination of rickettsia — In one well-controlled test the serum from one recovered case of the Montana infection gave results identical with one serum from a recovered case of *Q* fever when tested with a suspension of *Rickettsia burneti* prepared in Australia.

Protection tests — As far as these tests have been tried no immunological difference has been noted between the virus of *Q* fever and that isolated from Montana ticks.

legitimate by analogy with other infective diseases, to consider that this hypovitaminosis may play a considerable part. It is also possible to consider that B hypovitaminosis may be concerned with the vascular and perineural lesions. On these suppositions the authors attempted various combinations of vitamin treatment combined with other methods. They had previously found that mercurochrome and strychnine had proved useful and the treatment now advocated, after an experience of 40 cases, consists of intravenous administration of 2 cc. mercurochrome (1 per cent) daily for 5 or 6 days. Intravenous injections of 25 cgm. ascorbic acid (as Cebion, etc.) twice to four times daily. Administration of 10 mgm. vitamin B₁₂ (Betaxin intramuscularly) twice daily with lumbar puncture if the c.s.f. is under pressure and symptomatic treatment with subcutaneous glucose and ordinary cardiac stimulants.

Protocols of these experiments will be published later but in the meantime the authors state that excellent results have been obtained in this way in Addis Ababa. [See also SCAFFIDI above.] C II

THOMPSON (T O) Fevers of the Typhus Group in Northern India.—*Jl Roy Army Med Corps* 1939 Apr Vol 72, No. 4 pp 267-269

This note refers to an outbreak of fever in the Viceregal bodyguard at Dehra Dun in the hot weather of 1929. There were 7 cases with 4 deaths. The medical attendants attributed the fever to bites of ticks incurred while grazing horses in the neighbourhood. On investigation however it was discovered that the first patient was taken ill 4 days after he had returned from leave at his home in Kashmir State on one of the main trade routes through the hills [see BLEWITT this *Bulletin* 1939 Vol 36 p 481]. He had attended a festival 14 days before he developed fever. 10 to 12 days later 3 contacts developed fever and 3 more 10 days later. One case only was seen by the author. He had very high fever and was critically ill. Body lice were seen crawling away over the bedclothes. The patient died a few hours later. The inference is that the cases were true louse-borne typhus and not tick typhus. D H

CLEAVE (T L.) A Case of Typhus Fever.—*Jl Roy Nav Med Serv* 1939 Jan Vol 25 No 1 pp. 72-73 With 1 chart.

A case of typhus contracted in Shanghai and detected during transit to Hongkong. The Weil-Felix reaction was positive 1/840 for *Proteus OX19*. Two guinea-pigs inoculated with blood taken from the case both developed fever and a second guinea-pig inoculated from these also became infected. This work was carried out in hospital in Hongkong. D H

JORDAN (J H) & FLETCHER (A E.) A Note on Disinfestation with Particular Reference to Typhus.—*Chancs Med Jl* 1938. July Vol 54 No 1 pp 71-72

In a letter to the *Tropical Diseases Bulletin* the authors point out that in experiments it was found that ordinary cresylic acid or refined products such as Lysol, Izal, etc. were only slightly toxic to lice even with the addition of ammonia. An *empure* cresylic product containing

pyridine quinoline and naphthalene however had a lethal effect on lice if ammonia was added. This product was cheaper than the pure product and the mixture with ammonia was useful in bug infestation. They suggest that quinoline might prove worthy of investigation in regard to its use in disinfection. [See this *Bulletin* 1939 Vol. 36 p 472.] C II

DYER (R E) *Les maladies à Rickettsia aux États Unis [Rickettsial Diseases in the United States]*—*Bull Office Internat d'Hyg Publique* 1938 Dec, Vol 30 No 12. pp 2772-2774

Two Rickettsial diseases are endemic in the United States endemic typhus and Rocky Mountain spotted fever. In 1923 only 50 cases of endemic typhus were reported and all of these were in the coast towns of the south-eastern States. Since that date there has been a gradual increase in the numbers reported and it has spread from the towns to the country districts. 1,308 cases were reported in 1934 and in 1937 in Georgia alone more than 1 000 cases were reported. Practically all the small rodents natives of the southern States which have been examined have been proved to be susceptible to the virus. Spotted fever also is now no longer confined to the Rocky Mountains but is also found in the eastern States in Canada British Columbia and in Brazil. D H

KEMP (Hardy A) *Endemic Typhus Fever in Texas. An Epidemiological and Clinical Comparison with Forms of Typhus seen elsewhere.*—*Amer J Trop Med* 1939 Mar Vol 19 No 2. pp 109-129 [18 refs]

In Texas the disease attacks young male adults and in the temperate regions the cases occur in August and September. Most of the cases are in middle-class people who contract the disease not in their homes but at their work in shop or store. On the other hand poor whites contract the disease in rat infested houses.

The clinical description shows that the disease is similar to that met with elsewhere but the author insists that the disease is distinct from Brill's disease which ZINSSER has shown is caused by the classical virus. D H

LORANDO (N) & PAPANASTASSIOU (E) *Typhus endémique murine sans exanthème. [Endemic Typhus without Rash.]*—*Bull Soc Path Exot* 1939 Feb 8 Vol 32. No 2. pp 122-124

Two cases of fever occurred at the same time in the same house a man aged 45 and his mother aged 62. Both cases were typical and gave strong positive Weil-Felix reactions. A virus was isolated from the blood and produced fever and orchitis.

The two cases were similar except that in the older patient no sign of rash could be discovered although careful examination was made daily. In the case of the son the rash was profuse and typical. D H

LORENDO (N) Périorchite chez un malade atteint de typhus murin.
[Periorchitis in a Case of Murine Typhus].—*Bull Soc Path. Exot.*
1939 Jan. 11 Vol. 32. No. 1 pp. 17-18.

A case of fever with profuse typhus rash and Weil-Felix reaction positive for *Proteus OX19* in a dilution of 1/500 Just as the fever ceased on the 20th day a double orchitis developed with pain and tenderness the condition lasted for one week. D H

BRUNEAU (J) Un cas de typhus murin, isolement et identification.
[A Case of Murine Typhus, Isolation and Identification of the Virus].—*Rev Méd Française d'Extrême-Orient* 1938 Aug-Sept Vol. 20 No 7 pp 602-608. With 18 charts.

A case of fever in a European with typical rash and other symptoms. The Weil Felix reaction was positive for *Proteus OX19* Blood was taken during the fever and inoculated into guineapigs these reacted with fever and orchitis. Rickettsia were present in smears made from the inflamed tunica. The virus was passaged for 13 generations in guineapigs monkeys were also infected and when tested later were found to be immune to the viruses of murine typhus and true typhus.

D H

ZIA (Samuel H) LIO (P Y) & PANG (K. H.) Isolation of Typhus Rickettsia from Infected Animals on Zinsser Agar Tissue Media.—*Chinese Med J* 1938 Dec. Vol. 54 No 6. pp. 547-558 With 1 fig

The agar for culture of Rickettsia was prepared according to the directions of Zinsser

Take 150 cc double distilled water with 3.2 gm of sod chlor add

3 per cent. pot. chlor 4 cc.

3 per cent calc chlor 4 cc

1 per cent. mag chlor 4 cc

5 per cent sod bicarb. 4 cc.

0.5 per cent pot ac phos 4 cc.

Add 0.4 gm glucose

Horse or human serum 125 cc., filter

Tyrode double strength 100 cc.

Boil 4 per cent agar To 100 cc. agar add 110 cc of filtered

Tyrode+serum Add 10 cc 0.02 per cent phen red Tube

agar and slope 7.8 pH.

Three strains of murine Rickettsia were used, a Mexican strain, a strain from a local rat and from a local patient Small pieces of tunica, removed aseptically from infected rats, were placed on the surface of the agar tubes and incubated at 37°C Mouse embryo tissue was placed in the culture tubes and then transferred to new tubes of media for subcultures.

Smears were examined by staining as follows —

3 minutes phosphate buffer wash off.

4 minutes 0.25 per cent basic fuchsin in distilled water

Decolorize in 0.05 per cent citric acid.

Counterstain 5 secs with 0.25 per cent. aqueous methylene blue

Successful cultures were obtained from 38 guineapigs and 6 rats and subcultures were carried for several generations D H

ANIGSTEIN (Ludwik) & LAWKOWICZ (W) Researches on Strains of *Rickettsia* and *Proteus* cultivated from Experimental Typhus of the Murine Type.—*Trans Roy Soc Trop Med & Hyg* 1939 Feb 28 Vol. 32 No 5 pp 605-613 With 3 figs on 1 plate

The culture medium employed in this research was Noguchi's semi-solid agar medium [see LAWKOWICZ below] Two strains of murine typhus virus were employed one obtained from Tunis and the other from Poland. Tests showed that these two strains were identical. The inoculum was the blood and brain of infected rats and guineapigs. The cultures were incubated at 35°C for 5 days—8 strains were cultivated *in vitro* from these two strains growth appeared after 4 days incubation and consisted of masses of minute cocci or delicate rods. Six of these strains were definitely Rickettsial in appearance were non motile did not ferment any sugars and later grew well on chocolate agar. Two strains were definite bacilli more like *Proteus* these were motile and fermented carbohydrates with the production of acid and gas they were non indologenic. The 6 Rickettsia strains were agglutinated by immune rabbit serum to the same dilution the *Proteus* strains were not so agglutinated. Guineapigs infected by injection of living Rickettsial cultures were later shown to be immune to the virus of murine typhus from passage animals. Formal killed Rickettsial cultures were used to vaccinate rats and immunity was produced against murine typhus virus.

LAIGRET (Jean) & DURAND (Roger) Modification de l'activité pathogène de deux souches de virus typhiques murins entretenues par passages sur les souris blanches [Modification of the Pathogenic Activity of 2 Strains of Murine Typhus Virus during Passage in White Mice.]—*C R Acad Sci* 1939 Feb 27 Vol 208 No 9 pp 673-675

It has already been noted that the virus becomes much less virulent for guineapigs when passaged in white mice. But in the course of their investigation the authors found that if the peritoneal route is employed in the injection of the white mice paralysis is produced and these animals die. This condition is not produced either in rats or guineapigs by the passaged virus although in one or two rats high fever was produced. It was found that in most cases there was a large amount of virus in the brains of the paralyzed mice. This condition is compared with the neurotropic virus in mice in yellow fever.

ZIA (Samuel H.) LIU (P. Y.) & PAAG (K. H.) Isolation of Typhus Rickettsia from Infected Animals on Zinsser Agar Thermo Media.—*Chinese Med J* 1938. Dec Vol. 54 No. 6 pp 547-558 With 1 fig

The agar for culture of Rickettsia was prepared according to the directions of Zinsser

Take 150 cc double distilled water with 3.2 gm of sod chlor add

2 per cent. pot. chlor 4 cc.

2 per cent calc chlor 4 cc.

1 per cent mag chlor 4 cc

5 per cent sod bicarb. 4 cc.

0.5 per cent pot ac phos. 4 cc.

Add 0.4 gm. glucose

Horse or human serum 125 cc. filter

Tyrode double strength 100 cc.

Boil 4 per cent agar To 100 cc. agar add 110 cc of filtered

Tyrode+serum Add 10 cc 0.02 per cent phen red Tube

agar and slope 7.8 pH.

Three strains of murine Rickettsia were used, a Mexican strain a strain from a local rat and from a local patient Small pieces of tunica, removed aseptically from infected rats, were placed on the surface of the agar tubes and incubated at 37°C. Mouse embryo tissue was placed in the culture tubes and then transferred to new tubes of media for subcultures.

Smears were examined by staining as follows —

3 minutes phosphate buffer wash off.

4 minutes 0.25 per cent basic fuchsin in distilled water

Decolorum in 0.05 per cent citric acid

Counterstain 5 secs with 0.25 per cent aqueous methylene blue.

Successful cultures were obtained from 36 guineapigs and 6 rats and subcultures were carried for several generations D H

ANIGSTEIN (Ludwik) & LAWKOWICZ (W) Researches on Strains of *Rickettsia* and *Proteus* cultivated from Experimental Typhus of the Murine Type—*Trans Roy Soc Trop Med & Hyg* 1939 Feb 28 Vol 32. No 5 pp 605-613 With 3 figs on 1 plate

The culture medium employed in this research was Noguchi's semi-solid agar medium [see LAWKOWICZ below] Two strains of murine typhus virus were employed one obtained from Tunis and the other from Poland. Tests showed that these two strains were identical. The inoculum was the blood and brain of infected rats and guinea-pigs. The cultures were incubated at 35°C for 5 days—8 strains were cultivated *in vitro* from these two strains growth appeared after 4 days incubation and consisted of masses of minute cocci or delicate rods. VIOLLE (H.) Expériences sur le virus érythémateux murin. Sensibilité du rat aux urines virulentes d'origine humaine et murine [Experiments with Murine Typhus Virus. The Susceptibility of the Rat to Infected Urine of Man and Rats.]—*C R Soc Biol* 1938 Vol 129 No. 33 pp 864-868.

The author considers that rats were to be preferred to guinea-pigs for these experiments as they are more susceptible and are natural hosts of the virus.

Rats were fed on bread which had been soaked in the urine of rats infected with typhus and these animals became infected. Positive results were also obtained with food contaminated with the urine of a human patient suffering from endemic typhus. The usual symptoms were observed in the infected rats.

This is a possible mode of infection from rat to rat in nature and man may also be infected by the consumption of food soaked by the urine of rats. It is also suggested that the diagnosis of cases might be aided by the feeding of rats on food contaminated with the urine of patients. [See also this *Bulletin* 1938 Vol 35 p 782.] D H

GIROUD (P) & PANTHIER (R.) Comportement de la souris blanche à la suite de l'inoculation de virus typhique murin. [Behaviour of White Mice following inoculation of the Murine Typhus Virus.]—*Bull Soc Path Exot* 1939 Apr 4 Vol 32 No 4 pp 404-409 With 5 figs

If this virus is passed in white mice it gains in virulence for these animals but loses virulence for guinea-pigs. If the virus is then passed in guinea-pigs by the method of intraperitoneal injection of tunica washings the virulence is rapidly regained but virulence is lost for white mice.

The Zimmer virus causes death in 80 per cent of inoculated white mice in from 4 to 23 days. At the first passage death occurs from the 6th to the 14th day at the 2nd passage 4th to 5th day and 3rd passage in 32 to 100 hours. After the 4th passage convulsions occur in the mice lasting about 15 seconds and death follows.

Rickettsia-like bodies were seen in the peritoneal exudate and also in the liver and spleen of the mice. D H

RUIZ CASTAÑEDA (M.) El tifo de Zacoalco [Typhus in Zacoalco.]—*Medicina Mexico* 1939 Aug. 10 Vol 19 No 345 pp 301-303 French summary (7 lines)

The author describes a mild form of typhus which is common in Zacoalco, Jalisco and which had been considered clinically as a form

of typhoid fever. The fever is continuous for 10-12 days without rash. Blood from one of the patients was sent to Guadalajara and there found to agglutinate *Proteus* $\lambda 19$ and *Rickettsia prowazekii* and to give the Neill Mooser reaction in rats. Guinea-pigs immune to the strain L were immune to emulsions of the tunica of animals infected with the Zacualco strain and complete cross immunity was observed.

This strain therefore corresponds to the Mexican orchitic strain of exanthematic typhus probably of murine origin. No body lice were found in the neighbourhood but *P. capitis* was present. It is possible that transmission may occur from man to man through lice but the origin of the infection from rodents and their ectoparasites cannot be excluded. Investigation into its existence in rodents has not been undertaken. C H

IWATA (Shigeru) Study on Typhus Fever Of Types Varieties and Clinical Symptoms of Typhus Fever in Manchuria.—*Jl Oriental Med* 1939 May Vol 30 No 5 pp 183-220 With 1 map [61 refs]

The authors have examined a large number of strains of typhus virus isolated from cases in Manchoukuo. As a result of the effects of inoculation of these viruses into male guinea-pigs they found that they fall into 3 classes. The clinical picture as seen in the Table below corresponds with the laboratory findings.—

Virus

	Class I Murine	Class II Intermediate	Class III Epidemic
Scrotal reaction	Constant	Occasional	Absent
Mooser cells	Constant	Occasional	Absent

Clinical features

Fever	Mild	More severe	Severe and critical
Mental symptoms	None	Occasional	Delirium
Rash	Macular	Petechial	Petechial
Fatal cases	None	Few	Many

In one epidemic all three types of virus were isolated from cases of fever. D H

LÉPINE (P) A propos du typhus sans exanthème [Typhus Fever without Rash].—*Bull Soc Path Exot* 1939 Feb 8 Vol 32. No 2. pp 124-125

A mild case of fever lasting 8 days. The Weil-Felix reaction was positive in a dilution of 1/1600. Blood was taken from the patient and inoculated into a guinea-pig: there was no orchitis but *Rickettsia* were found in smears from the exudate. This case occurred along with other cases which were typical and which all showed a rash. D H

FERNANDO (Cyril F) Tropical Typhus.—*Jl. Ceylon Branch Brit. Med. Assoc.* 1938. Nov. Vol. 35 No. 6. pp 463-466. With 1 chart.

Two cases of fever with rash. The Weil-Felix reaction was strongly positive for *Proteus OX19* in one case in a dilution of 1/5000. It was negative for *OXK*.

Guinea-pig inoculation was positive but *Rickettsia* could not be found in smear from the swollen tunica. D H

[Disturbances of Chloride Metabolism in Epidemic and Murine Typhus].—*Rev. Service Santé Milit.* 1939. Feb. Vol. 110 No. 2. pp 197-206. With 10 charts. [Refs in footnotes.]

GEAR (J H S) South African Typhus.—*South African Jl. Med. Sci.* 1938. Oct. Vol. 3 No. 4. pp 134-160. With 10 figs. [26 refs.]

A general review of the subject in the light of recent work by the author and his colleagues. PIERCE and others as the result of research were inclined to the view that the viruses of typhus fever in South Africa differed from the viruses of similar diseases elsewhere. [See this *Bulletin* 1931 Vol. 28 p 101. 1932, Vol. 29 p 452, 779. 1933 Vol. 30 p 908. 1935 Vol. 32, p. 154, 168, 561.] For instance they found in the case of louse-borne typhus that the sera gave positive reactions only in low dilutions with *Proteus OX19* and also agglutinated *OX2* in similar or in some cases, higher dilutions. For endemic typhus similar serological results were obtained. Tick bite fever as observed by the same observers was noted as being the mildest of the typhus-like fevers with a constant primary sore or ulcer and was proved to be carried by larval ticks from veldt rodents to man. On the other hand RHOODES [this *Bulletin* 1935 Vol. 32, p 561] in his area of South Africa found that the Weil-Felix reaction in louse-borne typhus was positive, in some in high dilution up to 1/20 000 and in endemic typhus up to 1/4000.

Gear and his colleagues have examined a considerable number of cases of louse-borne typhus (as he says "beyond question one of the major problems confronting the health authorities of South Africa") and his serological findings are summarized as follows—

1 Agglutinins appear early and, before the end of the first week of illness, the titre has reached diagnostic levels. the maximum titre is reached at the end of the fever and is usually high, 1/12,000 to 1/25 000 are frequently observed.

2 *Proteus OX19* is generally agglutinated to higher titre than *Proteus OX2*. The agglutination of *OXK* is irregular and rarely occurs in high dilutions of serum. Louse borne typhus therefore falls serologically into the same group as classical European typhus.

As regards the effects of the virus on experimental animals it is noted that pneumonic changes in the lungs of guinea-pigs were frequently observed. *Rickettsia* were seen in the exudate from the spleen and orchitis although observed was very rare.

Only one case of murine typhus was investigated. this was an accidental infection in the laboratory the writer himself and has

already been reported in this *Bulletin* 1938 Vol 35 p 787. The virus was isolated from the blood and passaged in guineapigs. Orchitis was noted in over 90 per cent of the animals inoculated.

The author then refers to the classical type of tick bite fever as previously described by PIPPER and others. This is a very mild fever with constant primary sore and is carried by larval ticks and is contracted on the open veldt. The author however has noted recently in the city and suburbs of Johannesburg another type of the same disease which differs from the above description in several particulars. The fever is severe with delirium and on at least two occasions proved fatal. The primary sore is not constantly present but when found is a typical *tache noire* with lymphadenitis. This sore has been observed to occur in the conjunctiva. The disease is carried by the dog tick from the dog to its owner and in these particulars closely resembles *boutonneuse* fever of North Africa. Gear is of opinion that these are two types of the same disease the differences being due to the fact that in one case young people are infected by larval ticks (*A. hebraeum*) from veldt rodents in the other type older people are infected by dog ticks (*H. leachi*) from domestic dogs.

The author succeeded in cultivating the virus in egg media and noted that in certain cells the Rickettsia had invaded the nuclei of the cells as do the Rickettsia of Rocky Mountain fever. It was also found that the viruses of louse-borne typhus and endemic typhus are immunologically identical as are the viruses of the two types of tick bite fever. Tick bite fever virus does not protect against the typhus viruses but typhus virus shows some degree of protection against tick bite fever virus.

His conclusions are as follows —

In clinical symptoms serological reactions and course of the disease in experimental animals South African louse-borne typhus resembles the classical disease and the one case of murine typhus examined resembled cases of murine typhus described in other parts of the world.

The South African variety of tick typhus—tick bite fever—resembled other varieties of tick typhus namely Rocky Mountain spotted fever and *fièvre boutonneuse* in the serological reactions and in the morphology and distribution of the Rickettsia. Especially noteworthy were the nuclear infections seen in tissue and egg cultures. The disease is milder in South Africa than elsewhere. D H

GEAR (James) Complications in Tick-Bite Fever. A Survey of Fifty Cases.—*South African Med J* 1939 Jan. 14 Vol. 13 No 1 pp 35-36

Tick bite fever as observed by the author in the Witwatersrand is a severe and on occasions a fatal disease in which the following complications have been met with: general thrombosis, pulmonary embolism, bronchopneumonia, retinal haemorrhages, slight albuminuria in most cases and in one case with previous history of renal disease, uraemia. Severe conjunctivitis was noted in three cases and was due to primary infection in the eye caused by blood from infected ticks removed from dogs.

Three fatal cases were reported and two other fatal cases were investigated. In one the Weil-Felix reaction was positive there was a profuse and typical typhus rash and a definite primary sore was

noted on the head with inflamed glands in the neck in the second fatal case the blood of the patient infected guinea-pigs and a virus was isolated D H

FITZPATRICK (Florence K.) Agar Slant Tissue Cultures of Spotted Fever Rickettsiae.—*Proc Soc Experim Biol & Med* 1938. Dec Vol 39 No 3 pp 501-502 With 1 chart.

A case of spotted fever Eastern type was reported from Cape Cod, Massachusetts. Blood was taken on the 8th day of the illness and injected into two guinea-pigs—one of these developed fever.

The virus was passaged to other animals these reacted with fever and scrotal reaction but no necrosis there was no mortality among the inoculated animals but later these were shown to be immune to a virulent strain of Rocky Mountain fever. The tissues of infected guinea-pigs were cultured on agar slopes and subcultured by means of mouse embryo tissue. There was a very rich growth of Rickettsia and guinea-pigs were infected from the cultures. D H

BAUERFIELD (E Herbert) Rocky Mountain Spotted Fever with Unusual Features.—*Am J Med Assoc* 1939 May 6 Vol 112 No 18 pp 1819-1820

The unusual features in this case were that the rash resembled a typhus rash rather than spotted fever. The rash did not appear till the 9th day instead of the 4th or 5th it was confined to the trunk and was petechial and the patient also developed jaundice which is not usually seen in the Eastern type of spotted fever. There were no other cases in the neighbourhood but the patient's husband had returned from hitch-hiking in Florida 10 days before the illness commenced and she had removed ticks from his person. The patient died. D H

PHILIP (Cornelius B.) & DIAS (Emmanuel) Rocky Mountain Spotted Fever. Failure of Triatomid Bugs to transmit the Virus Experimentally.—*Mem Inst Oswaldo Cruz* 1938 Vol 33 No 4 pp 473-476 [Portuguese version pp 489-472]

The Montana strain of the virus of Rocky Mountain fever was employed in these experiments and bugs of four different genera were tested. Transmission was attempted by feeding on infected guinea-pigs and then feeding on clean guinea-pigs after varying intervals up to 100 days interrupted feeding was also tried and the fed bugs were also ground up and injected.

The result of the experiment shows that these bugs can neither transmit the virus by their bites nor retain virulent virus in their bodies for longer than 2 to 4 days. [See also this *Bulletin* 1938 Vol 35 p 786] D H

DE MAGALHÃES (Octavio) Tifo exantemático em Minas Geraes—O vírus. Algumas propriedades. [Properties of the Virus of Exanthematic Typhus in Minas Geraes].—*Acta Med Rio de Janeiro* 1939 Apr Vol 3 No 4 pp 203-216 With 2 charts. English summary.

On the strength of his own experiments the author concludes that the exanthematic typhus virus of Minas Geraes is of an easy manipulation. It is easy to be isolated from the blood both of human

patients and of inoculated animals when in the febrile period. When they are in the incubation period, their blood as a rule is not infectious or rarely produces transient and benignant disease. There were exceptional cases in which the blood was infectious 24 hours after inoculation. In human blood the author found the virus up to the 18th day of the disease on examining the rare surviving cases. The author encountered the virus, in natural state in wild rabbits (pred opossum ticks (A. cajennense) and bedbugs (C. lectolaris). He states that the spleen is the organ which contains the largest quantity of the virus. In the central nervous system the virus remains a long time up to 60 days when the virus is already not found in the circulating blood and the temperature is low. The virus cooled down to -5 or -10°C has kept its initial virulence up to 160 days after its removal from the animal. When the author operates on the nervous system great care has to be taken because there appear tissue changes giving origin to substances which are toxic to the animals. At ordinary temperature the virus lost quickly (96 hours) the virulence. The author verified the passing of the virus through placenta to Rhesus the fetus of which presented typical changes of the disease. He also verified that the virus does not pass through healthy skin even when shaved, and therefore direct contagion should be very rare. At temperatures above 50°C . the virus dies quickly and at 100° instantaneously. A good medium for the preservation of the virus during some days is glycinated gelatin taking care to avoid its contamination by bacteria or fungi. The action of radium or X rays on the virus is none or nearly none. The virus dried in vacuum is able to be virulent up to 7 days but there are variations in accordance with the sample. The reinoculation of the virus through transmitting arthropods considerably increases its virulence. The virus seldom passes through an L5 filter candle. Employing the current technique it is cultivated very well on the chorio-allantoic membrane of the chick's embryo.

DE MAGALHÃES (Octavio) *Tifo exantemático em Minas Gerais. Diagnostico* (13a comunicação) [Typhus Fever in Minas Gerais. Thirteenth Communication. Diagnosis]—Reprinted from *Acta Medica* Rio de Janeiro 1939 Jan Vol 3 No 1 13 pp With 1 chart English summary (8 lines)

Diagnosis of typhus fever is based on (1) Clinical signs and symptoms (2) Epidemiological state (3) Laboratory tests (4) Pathological anatomical findings (5) Isolation of virus and inoculation into a susceptible animal. Considering the question generally the author concludes that in severe and typical cases clinical evidence is enough but in mild abortive or hyperacute cases (*Typhus siderans*) such evidence is not satisfactory and there is need of one or more of the other investigations noted.

COOLEY (R. A.) *The Genera Dermacentor and Otocentor (Ixodidae) in the United States, with Studies in Variation.*—*National Inst Health Bull* No 171 Washington 1938 Dec. pp v+89 With 30 plates (9 coloured) & 8 figs. [Bibliography] 1938. Washington Govt. Printing Office [\$1 25]

BRUNEAU & CHAPUIS *Observation et étude expérimentale d'un cas de tsutsugamushi à Hanoï. [Observation and Experimental Study of a Case of Tsutsugamushi Fever in Hanoi.]—Rev Méd Française d'Extrême-Orient* 1938. Aug-Sept Vol. 20 No 7 pp 907-912. With 7 charts

A severe case of fever lasting 18 days with a typical primary sore in the umbilical region. Two guinea-pigs were inoculated with blood

taken on the 14th day of the fever and both died post-mortem examination showed the usual signs of tsutsugamushi infection. The Weil-Felix reaction of the blood of the patient was positive for *Proteus* OXA 1/1000 but negative for OX19 and OX2. Rabbits inoculated with blood into the anterior chamber of the eye gave the typical reaction of iridocyclitis and keratitis with continued fever D H

GUNTHER (Carl E. M.) & SCHROEDER (A. G.) Further Observations on Endemic Typhus in New Guinea.—*Med J Australia* 1939 May 6. 26th Year Vol 1 No. 18 pp 688-691 With 1 map

In the appendix to this paper the synonym for endemic typhus is "Japanese River Fever"

Two further cases are described in the present paper both in white people in one case which was fatal the Weil-Felix reaction was positive for *Proteus* OXK in a dilution of 1/2500. Since 1934 46 cases have been reported in this district with a mortality of 20 per cent. All the cases were in white people none has so far been reported in natives. The whole district is heavily infested with mites and also with bush rats. With a view to prevention clearing of paths is suggested and removal of mites by bathing if a primary sore is detected excision of the ulcer is recommended. D H

WIJERAMA (E. M.) Notes on Two Cases of Tropical Typhus.—*Jl Ceylon Branch Brit Med. Assoc* 1938 Nov Vol 35 No 6 pp 467-468.

Two cases of fever without rash or primary sore both were dark skinned people one an Indian, the other a Sinhalese. The Weil-Felix reaction was positive in both cases in a dilution of 1/5000 for *Proteus* OXK negative for OX19. A guinea pig inoculated with the blood of one case developed fever and orchitis and Rickettsia were demonstrated in films from the tunica. D H

their men or nearly all had been vaccinated cases of typhus occurred among the vaccinated. Some of these were reactions following the administration of the vaccine (mild attacks of murine typhus) but others were cases of typhus (epidemic) in recently inoculated people. These failures they attribute to two causes (1) that it is impossible to keep the virulence of the vaccine (murine living typhus virus) constant and (2) that the vaccine if kept too long loses its efficacy. It is suggested that the difficulties might be overcome by using as vaccine the virus in the dried excreta of fleas. D H

GAUD La vaccination contre le typhus exanthématique par la méthode de G. Blanc au cours de l'épidémie de 1938 au Maroc [Vaccination against Typhus by the Method of G. Blanc during the Epidemic of 1938 in Morocco]—*Bull. Office International d'Hyg. Publique* 1939, Dec. Vol. 30 No. 12 pp. 2751-2758 With 2 graphs.

The epidemic started in November 1937 and vaccination was commenced in December and approximately 150 000 people were inoculated each month in Casablanca so that by May over one million people had been vaccinated [see *Bull. Inst. d'Hygiène du Maroc* above, p. 883].

Conclusions are that in districts where typhus breaks out and the majority of the people have been vaccinated the epidemic is arrested. In mixed populations where Europeans and natives are living together typhus cases are much more numerous among the natives but if the native population is vaccinated and the Europeans are not then typhus cases are more numerous among the latter also in places where the people have already been vaccinated cases are few whereas in non vaccinated places there are numerous cases and small epidemics. This vaccine has now been tested in Morocco with satisfactory results. [See this *Bulletin* 1937 Vol. 34 p. 486.] D H

MARIANI (G.) Vaccinazioni contro il tifo esantematico eseguite nel 1938 sull'altipiano etiopico con il vaccino Weigl. [Weigl's Vaccine in Prophylaxis of *Typhus exanthematicus* in the Ethiopian Highlands in 1938.]—*Ann. d'Igiene* 1939 May Vol. 49 No. 5 pp. 316-322.

Over 13 000 vaccinations were performed 2 404 of the subjects being military and 10 672 civilians. Three injections were given at 3-day intervals. In the vast majority the reactions were very slight locally in 95 per cent. there was slight redness and swelling with a little pain coming on 6-12 hours after and lasting 2-4 days less marked after the second and third injections. As for general reactions 20-25 per cent. showed a rise of temperature of $\frac{1}{4}$ -1 degree and some headache rarely did the fever exceed 38.5°C. A few cases were seen among the vaccinated and these ran a mild course with one exception in this case death occurred but infection had been acquired before vaccination was begun. Four others were down with the disease before the vaccination was completed that is, they were vaccinated in the incubation period. H H S

ZINSSER (Hans) FITZPATRICK (Florence) & WEI (Hsi) A Study of *Rickettsias* grown on Agar Tissue Cultures.—*Jl Experim Med* 1939 Feb 1 Vol 69 No 2 pp 179-190 With 3 charts [11 refs]

Agar slopes are prepared with double strength Tyrode solution with horse serum. Small pieces of infected tissue were placed on the surface of the agar and profuse growth of *Rickettsia* were obtained both of murine typhus and historical typhus. These *Rickettsia* are readily stained by carbol fuchsin and counterstained with methylene blue—see paper by ZIA, LIU & PANG above p 992

Subcultures were readily obtained by mixing normal mouse embryo tissue with the infected tissues and inoculating new tubes with this.

Inoculations with cultures after 18 months always produced typical reactions in guineapigs and these animals when tested later were immune to passage virus.

Animals inoculated with phenol or formal killed vaccine from agar cultures were also immune to test doses. By this method of culture large amounts of *Rickettsia* of classical typhus can be obtained and vaccines prepared. [See also this *Bulletin* 1939 Vol 33 p 363]

VENTENTILLAS (Fcha) Vaccination against Typhus Fever with the Zinsser-Castaneda Vaccine.—*Jl Immunology* 1939 May Vol 36 No 5 pp 339-348

The vaccine used in this work was an emulsion of formalized *Rickettsia* from irradiated rats (Zinsser's method) the strength of the vaccine was 5 000 million organisms per cc. Doses of vaccine were given at weekly intervals to 12 people. These people were later tested with doses of virus using 25 times the minimum infective dose for a guineapig and estimated as 2 000 minimum infective doses for man. Three of these people showed slight fever only. One dose of the vaccine protected guineapigs against the murine virus but not against the classical virus but 3 or 4 doses of vaccine protected against this virus also.

It is proposed to use this vaccine on a large scale in Bolivia where prevention by sanitary methods is exceedingly difficult.

PRICE'S OF ABSTRACTS IN THIS SECTION

RICE (p 1003) claims to be able to detect differences in virulence between various strains of benign tertian parasites by means of complete tests of liver function.

RUSSELL and MOHAN (p 1004) describe the staining of oöcysts in living mosquitoes.

VAN THIEL *et al* (p 1004) proved by experiment that *A. maculipennis atroparvus* of the Dutch race is definitely zoophilic towards the pig, but that Italian *labranchias* and *clutus* are anthropophilic. The keeping of pigs is therefore only useful against *atroparvus* in the Netherlands.

CORRADETTI (p 1005) details the Anopheles found in different parts of Abyssinia. From extensive dissections IVENGAR (p 1005) found that *A. philippinensis* in the plains of Bengal and *A. minimus* in the foothills are the most important vectors. RUSSELL *et al* (p 1005) record the simultaneous finding of infected *A. subpictus* and *A. vagus* in Madras. In S Travancore MATHEW (p 1005) found most infection in *A. fluviatilis* and less in *A. varuna* and *A. culicifacies*. PINTO (p 1006) gives an account of the damage done in S America by the introduction of *A. gambiae* from Africa and of its breeding habits. DAS GUPTA (p 1006) records abnormal forms of *P. vivax* seen in the blood of an infant 15 hours after birth.

SARROUY and PORTIER (p 1007) report an Arab girl with fatty nephrosis in the aetiology of which they consider that quartan malaria played an important part. MELCHIOR and ÖZKAN (p 1007) discuss malaria in relation to surgery. SOKHEY (p 1008) uses Folin's reagent in a test for plasmoquine in tissues but it cannot be used with urine.

A note is made of a conference of railway malaria inspectors in India (p 1008). A review of the literature on clover in relation to malaria is compiled by ROSEVEARE (p 1008). MANSON (p 1009) discusses the larvicidal action of various Assamese plants. BRYK and DAS CHOWDHURY (p 1009) show that 0.75 per cent of ammonium sulphate prevents mosquito breeding but as a general measure this would be too costly.

HEWITT (p 1009) details a technique for demonstrating avian malaria parasites in tissue sections. He (p 1010) concludes from experiments on birds that merozoites of *P. cathemerium* enter young red cells. When these are few in number multiple infections are common and *vice versa*.

STAUBER (p 1010) found that environmental temperature and period of rest and sleep were effective in modifying the time of segmentation of bird malaria parasites. HUFF (p 1010) shows that the segmentation of malaria parasites in birds is not associated with a rise in body temperature such as occurs in man. The rapid fall in numbers of *P. cathemerium* at the crisis of the initial attack was shown by BOYD (p 1011) to be due to lowered multiplication and increased destruction which are evident after the third or fourth day.

MANWELL and GOLDSTEIN (p 1011) consider that exoerythrocytic schizonts are merozoites accidentally ingested by cells of the reticulo-endothelial system.

RODRIGUES (p 1011) found streptomycin to be efficacious in *P. knowlesi* infections of monkeys. CHOPRA and DAS GUPTA (p 1012) consider that M & B 693 is more effective than atabrin in *P. knowlesi* infections of apes.

SARROUY & PORTIER. Néphrose lipoidique et paludisme [Fatty Nephrosis and Malaria].—*Bull et Mém Soc Méd Hôp de Paris* 1939 Apr 3 55th Year 3rd Ser No 11 pp 561-566

This is a detailed description of the case of an Arab girl aged 14 admitted to hospital in Algiers with generalized oedema and bad general condition. A year previously violent daily attacks of fever with shivering were followed by painful swelling of the lower extremities. Thereafter attacks of fever occurred at irregular intervals but the swelling persisted. The general condition was not seriously impaired however and the child lived a normal life until treated. A month before admission the condition was aggravated daily fever occurred with generalized oedema and diarrhoea. The albuminuria varied at different examinations from 4 to 28 grammes per litre. There was abundant urine from 30 to 35 grammes of urea were passed a day. Blood examination revealed the albumin content down to 40 gm per 1000 with inversion of the albumin/globulin ratio increase of total lipoids to 20.4 gm and an increase of cholesterol from 1.70 on admission to 7.50 gm. Neither casts nor blood cells could be found at any time in the centrifuged urine. Blood chlorine remained within normal limits even at times of greatest oedema. Blood urea generally low among vegetarian natives was as high as 0.77 gm per 1000 on admission. Ambard's constant was normal and arterial tension was not high. In the blood were found rosettes of *P. malariae* but no young forms. Malarial treatment followed by an intensive treatment with raw calf's liver effected some improvement. Blood urea fell the oedema diminished and there was an improvement of the cardiac condition. The patient left hospital before thyroid treatment which was to have been tried could be given. The author considers that malaria played an important part in the aetiology of this fatty nephrosis syndrome in which the renal function was unimpaired.

MELCHIOR (Eduard) & ÖZKAN (Adil). Malaria und Chirurgie. [Malaria and Surgery].—*Schweiz Med Woch* 1939 July 15 Vol 69 No 28 pp 640-642

The authors are working in Turkey and in Anatolia from which district their clinic receives cases. malaria plays a very important rôle. They discuss the subject under four headings. Firstly they consider the provocation of malaria by operations and accidental trauma. the differential diagnosis is particularly important when the malarial attack occurs in persons with infected wounds. As the malarial parasites may not be found in the peripheral blood in all cases it may be necessary to fall back in such cases, on a therapeutic diagnosis by administration of quinine. Secondly the confusion of acute appendicitis with an attack of malaria is dealt with and a case illustrating this point is detailed. Thirdly the surgery of the malarial spleen is discussed. the authors consider that the chief indications for splenectomy are torsion and splenic rupture. They do not favour splenectomy in malarial cachexia. Lastly the influence of malarial

cachexia on surgical mortality is dealt with. They find that resection of the large intestine is liable to be followed by death in patients suffering from malarial cachexia, and there was no other discoverable cause of death. They note that tabes and general paralysis are rare, probably causally related to the high incidence of malaria in the districts. On the question of whether the rarity of post-operative thrombosis and embolism in their cases can be ascribed to the same cause they are not prepared to express an opinion.

E. D. W. Greig

BOMBAY. REPORT OF THE HAFKINS INSTITUTE FOR THE YEAR 1937
[SOKHEY (S. S.) Director]—A Colorimetric Test for Plasmoquine
[NANDI & DIKSHIT] p. 44.

If a few drops of Folin's phenol reagent be added to an aqueous acid solution of plasmoquine and the mixture made strongly alkaline with Na_2CO_3 , a blue colour develops increasing to maximum intensity in about half an hour. The test can detect plasmoquine in a dilution of 1 in a million and can be used for quantitative estimations in dilutions up to 1 in 200,000. The test can also be used for the detection and estimation of plasmoquine in tissues if the latter be treated with an excess of NaOH and extracted with ether to get rid of phenolic compounds, the sodium salts of which are very soluble in water but insoluble in ether. The test cannot be used for the detection of plasmoquine in the urine. [See also this *Bulletin* 1939 Vol. 38 p. 580.]

A. W.

KHARGPUR, B. N. RAILWAY. Report of the Proceedings of the Third Annual Conference of the B. N. Railway Malaria Inspectors held on the 21st February 1938.—83 pp. 1938. Calcutta.

Like most reports of conferences this does not lend itself to summary nor is a summary generally necessary. Nearly all important additions to knowledge reported to conferences find their way independently into the scientific press. This report of a conference of Malaria Inspectors of the Bengal Nagpur Railway has an interest all its own. Quite apart from the local interest and importance of the observations recorded which in many instances are very considerable, it reveals a scientific outlook, powers of observation and an enthusiasm possessed by a team of Malaria Inspectors which must rob the arduous daily round of much of the monotony which it would otherwise possess. The subjects discussed include man-made malaria, the yellow fever menace to India, financial aspects of species control, malaria control on railway constructions, resting habits of adult mosquitoes, and anopheline breeding of many of the species of importance in the territory served by the Railway. The discussions on all these subjects were mostly confined to descriptions of personal observations made by contributors—a precedent worth following.

A. W.

ROSEVEARE (G. M.) Clover and Malaria.—Reprinted from *Herbage Reviews* Aberystwyth. 1939 June. Vol. 7 No. 2 pp. 90-93 [19 refs.]

This is a short review of the subject of *Melilotus* and its possible action in prevention of malaria. The idea was strongly advocated by

D HERELLE some 12 years ago but Bruce MAYNE's experiments showing that coumarin has no plasmodicidal value in mosquitoes and that the low prevalence of malaria in clover districts might be equally well explained by the drainage necessary for proper growth of the clover have now exploded the idea. This review though bringing forward nothing new is useful for reference on a subject now almost a matter of history.

H H S

MANSON (D) The Action of Certain Assamese Plants as Larvicides.—
Jl Malaria Inst of India 1939 Mar Vol 2. No 1 pp 85-83

The conclusions of this paper are as follows —

Duranta, *Zanthoxylum*, *Gardenia* and *Tephrosia* are valuable for their larvicidal action and can be used with success in water where there is no high velocity of flow and in ponds and swamps.

These plants all grow in Assam in profusion and can be used as auxiliary larvicides to oil and paris green in suitable situations. *Duranta* is also an excellent shade plant for malarialogenic drains. *Polygonum* is useful as a shade plant for small surface drains. *Tephrosia* may also be included in the same category. *Gardenia* and *Zanthoxylum* while excellent larvicides are not useful for shade planting but only for their larvicidal action. The larvicidal action of acetone dilutions of the seeds of *Tephrosia vogelii* is very marked and is due to Degueline, an isomer of Rotenone.

BRINK (C J H) & DAS CHOWDHURY (D K.) Ammonium Sulphate as a Combined Fertilizer and Mosquito Larvicide {Abstract}—
Jl Malaria Inst of India 1939 Mar Vol 2. No 1 pp 111-112

Experiments have shown that mosquito breeding cannot take place in water that contains 0.75 per cent. or more of ammonium sulphate. Observations were made with *Culex fatigans* and *A. stephensi*. Questions of cost would prohibit attempts to control mosquito breeding with ammonium sulphate in any large irrigation area.

N IV

HEWITT (Redginal) A Staining Technique for Demonstrating Avian Malaria Parasites in Tissue Sections—*Amer Jl Hyg* 1939 May Vol 29 No 3 Sect C. pp 115-117

The technique described consists of fixation in Zenker's fixative containing 5 per cent. of formal the mordanting of the sections in 2.5 per cent. potassium bichromate solution for one-half to one hour and, following a quick wash in distilled water staining for 24 hours with Wolfbach's Giemsa mixture (distilled water 100 cc 0.5 per cent. Na_2HCO_3 [so given in the text ? NaHCO_3] solution 2-4 drops methyl alcohol 3 cc Giemsa stain 2.5 cc). The sections are washed in distilled water coloured lemon yellow with the above bichromate solution differentiated in 70 per cent. alcohol (30 seconds to 2 minutes) and then dehydrated with graded xylol acetone mixtures up to pure xylol and mounted in balsam or cedar oil.

HEWITT (Redgmal) Experimental Erythroblastosis in Canaries and its Effect on Infections with *Plasmodium cathemerium*.—*Amer J Hyg* 1939 May Vol 29 No 3 Sect. C. pp 135-148. With 2 figs [15 refs.]

By the administration of phenylhydrazine solution to canaries, either orally on a number of days or intravenously, on one day a rapid destruction of red blood corpuscles is brought about, followed by the appearance in the blood of large numbers of immature red cells. Birds with this experimental erythroblastosis were inoculated with *Plasmodium cathemerium* and the resulting infection was compared with that produced in normal canaries. It was noted that in normal birds few young red cells are present while the number of cells with multiple infections is great at the start. The cells with three or more organisms are destroyed during their growth, only those cells with one or two organisms surviving. In the phenylhydrazine-treated birds there are many young red cells and in consequence only few with multiple infections. There is thus less parasite destruction and a more rapid rise in the parasite number which reached a higher peak than in the normal birds. The argument is that the merozoites enter young red cells. When these are few in number multiple infections are common, whereas when they are plentiful multiple infections are rare. [See also this *Bulletin* 1939 Vol 36 p 585]

C M H

STAUBER (Leake A) Factors Influencing the Asexual Periodicity of Avian Malaria.—*J Parasitology* 1939 Apr Vol 25 No. 2 pp. 95-118 With 7 figs [31 refs.]

Working with strains of bird malaria parasites which showed some regularity in the synchronism of reproduction, attempts were made to modify the time of segmentation by changes in temperature, light, feeding, host activity and rest and it was found that the environmental temperature and the period of rest and sleep were effective. Light acted only through the eye in that it rendered the host active. The young trophozoites were the forms of parasite chiefly influenced and it was the effect of the changes on them which determined the change in the time of subsequent schizogony. As there is a marked difference in the temperature of the active and the resting canary it seems that this temperature change which occurs when the bird passes from a condition of rest to one of activity or *vice versa* or some physiological condition which underlies it is the factor which determines the actual synchronism.

C M H

HUFF (Clay G) Relations between Malarial Infections and Body Temperatures in Canaries.—*Amer J Hyg* 1939 May Vol 29 No. 3 Sect. C pp 149-154 With 1 fig [11 refs.]

Though considerable fluctuations in the temperature of birds occur normally a notable feature being a rapid rise of temperature on awakening it was not possible to show that the presence of reproducing malarial parasites influenced the temperature. Four strains of parasite were tested in canaries but there was a complete absence of paroxysmal temperature rises at the time of segmentation of the

parasites This is in striking contrast to what obtains in man and mammals generally where the segmentation of malarial parasites is associated with marked rises in temperature C M II

BOYD (George H) A Study of the Rate of Reproduction in the Avian Malaria Parasite, *Plasmodium cathemerium*.—*Amer Jl Hyg* 1939 May Vol 29 No 3 Sect C pp 119-129 With 3 figs [11 refs.]

Working with *Plasmodium cathemerium* infections in canaries the author has observed that the largest groups of merozoites are formed by schizonts during the early stages of an infection The early schizonts produce on an average about 16 merozoites but the size of the schizonts diminishes till by the fourth day only about 12 merozoites are produced There is a slight increase on the seventh day but the original number of 16 merozoites is not again reached. Parasite destruction is low at the commencement of an infection but on the third day may involve 90 per cent of the parasites produced This level of destruction was maintained throughout the period of observation Thus the rapid fall in numbers of parasites at the crisis of the initial attack is due to the combined effect of lowered multiplication rate and increased destruction C M IV

MANWELL (Reginald D) & GOLDSTEIN (Frederick) Exoerythrocytic Stages in the Asexual Cycle of *Plasmodium circumflexum*.—*Amer Jl Trop Med* 1939 May Vol 19 No 3 pp 279-295 With 3 plates. [17 refs.]

The paper describes the presence of exoerythrocytic schizonts in the case of *P. circumflexum* infections in canaries This brings to five the number of species of bird malarial parasite in which these forms have been found the others being *P. cathemerium*, *P. praecox* (relictum), *P. elongatum* and *P. gallinaceum* all except the last named being inoculable to canaries The authors express the opinion that the occurrence of these schizonts is accidental and is due to the chance ingestion of merozoites by the cells of the reticulo-endothelial system. The same merozoites if they had entered red blood corpuscles would have developed into ordinary pigmented schizonts. It is thus the host cell which determines the size of the schizont and the number of merozoites produced. C M IV

RODHAIN (J) Paraaminophenylsulfamide et plasmodium des singes [*p*-Aminobenzinesulphonamide and Monkey Plasmodium].—*Ann Soc Belge de Méd Trop* 1938. June 30 Vol. 18 No 2. pp 255-258

During the treatment of two chimpanzees for a bronchitic infection with streptine (*p*-aminobenzinesulphonamide) it was observed that a simultaneous infection with malarial parasites of the *P. falciparum* type (*P. reichenowi*) was eradicated. This chance observation led the author to test the action of the drug on *P. knowlesi* infections in rhesus monkeys It was found to be equally efficacious in its action against this parasite though not so active as atebm. C M IV

CHOPRA (R. N.) & DAS GUPTA (B. M.) M. & B. 683 (2-Sulphanilyl-aminopyridine) in Ape Malaria.—*Indian Med. Gaz.* 1939 Apr Vol. 74 No. 4 pp. 201-202.

The conclusion reached by the authors is that M. & B. 683 unlike protosol and solnaeptasme is capable of curing monkeys of a *Plasmodium knowlesi* infection, as judged by the failure to relapse (examination of thick films) after a five-day course. The drug was administered intramuscularly in oily suspension, the daily dose varying from 0.05 gm. to 0.15 gm. It appears to be superior to atabrin for this infection for though there is a marked immediate action with atabrin, relapse almost invariably occurs in 10 to 15 days with rapid multiplication of parasites and death of the host if further treatment is withheld.

LEPROSY

PARCels OF ABSTRACTS IN THIS SECTION

LOWE (p. 1013) gives an account of certain leprosy legislation introduced in India at the end of the 19th century. POOTH (p. 1014) gives an account of leprosy in mediaeval West Pomerania.

LOWE and CHATTERJI (p. 1015) studying seasonal variations in clinical and bacteriological activity found this to be increased in the hot season in Calcutta to end abruptly with the onset of the rains.

In a region of the Congo DEGOTTE (p. 1016) found a disease rate of 44.37 per 1 000. This high rate is favoured by deficient sanitation and prolonged contact with cutaneous cases. In Panama beyond the Canal Zone, the rate found by COURTNEY (p. 1016) was 0.26 per 1 000. The disease appears to be familial and he postulates inherited predisposition in addition to prolonged contact.

In New Caledonia KERVIGNANT and BARI (p. 1016) conclude from a recent survey that leprosy is stationary in the natives and diminishing in the Europeans. The improved methods of prophylaxis include 10 agricultural colonies with good social and medical facilities. The outlook is much better than formerly. CELENTO (p. 1017) shows that in Queensland more cases have been detected recently than before owing to legislation giving power to examine suspects and contacts. There was a serious outbreak in Western Australia in 1933-1936 but DAVIS (p. 1017) reports that it is now well under control.

IXVES (p. 1018) reports a hopeful attempt to control leprosy in the British Solomon Islands by means of a colony system with outlying dispensaries, as at Urukoli in Nigeria.

MUIR (p. 1018) considers that leprosy attacks especially primitive people coming into social and industrial contact with more civilized races.

RYRIE (p. 1018) advises a mobile leprosy unit for surveys in Malaya, and points out that compulsory institutionalism is responsible for much of the

BERTRAM

(p. 1019) working with Kedrowsky's bacillus

reduced grafts
patients, &

tuberculosis.

with tuberculoid
to new tuberculoid

lesions. He failed to infect rats with human leprosy material emulsified in a number of different ways. SUZUKI (p 1019) reports increase in numbers of leprosy bacilli after intraperitoneal inoculation of animals.

McKINLEY (p 1020) reviewing the history of attempts at cultivation of the leprosy bacillus considers that up to 1917 the organisms grown could not be regarded as the true leprosy organism. He describes his own technique and SCOTT in comment carries the account further to include the Calcutta experiments and McKinley's own recent work. Suwo and KIN (p 1021) report multiplication of leprosy bacilli in tissue cultures of leprosy nodules. ROUSSEAU and GAUGEAT (p 1021) claim to have cultivated the human leprosy bacillus on Loewenstein's medium. EVANS (p 1021) isolated chromogenic mycobacteria on Clegg's medium which are considered possibly to be leprosy bacilli.

OBERDORFFER (p 1021) repeats his theory that the plant *Collocasia antiquorum* predisposes to leprosy when used as food. LOWE and CHATTERJI (p 1015) were unable to confirm this hypothesis in Calcutta.

RADNA (p 1021) discovered that patients with lepromata may excrete leprosy bacilli in the urine if undergoing treatment (for yaws or syphilis) with novarsenobenzol. He (p 1022) reviews the possible ways by which the bacilli may be eliminated from the body and their importance in transmission. He further (p 1022) as a result of house enquiries made regarding lepers concludes that family contact constitutes the greatest danger and may take place in a number of ways. Hereditary transmission is probably not important [see COURTNEY above]

LOWE (J) A Curious Chapter of the History of Leprosy in India
the Indian Leprosy Commission of 1890—*Leprosy in India*
1939 July Vol 11 No 3 pp 82-88

In 1887 the Government of India decided that efforts should be made to control leprosy and set about obtaining information as to the number of leprosy institutions there were the numbers of inmates the rules as regards separation of sexes etc. Institutions were few and were mostly temporary halting places for vagrant leper beggars. In order to stamp out the disease the conclusion was reached in 1888 that the sexes would have to be separated and all lepers confined for life. This being of course out of the question the only practicable measure was to give medical and charitable relief in voluntary hospitals and asylums. The following year however the Legislative Department prepared a draft bill for compulsory detention of all vagrant lepers and correspondence on this resulted in the appointing of a Commission to investigate the problem of leprosy in India. This Commission consisted of five members three selected in England by the National Leprosy Fund authorities (this fund was a memorial to Father Damien who had recently died in Hawaii) and the Royal Colleges of Physicians and Surgeons and two by the Government of India. The former three were Dr Beavan N RAKE of Trinidad, Dr G. A. BUCKMASTER and Dr A. A. KANTHACK and the two from India were Surgeon Majors A BARCLAY and S. J. THOMPSON I.M.S. Of the first three only Beavan RAKE had had any experience in leprosy and he was a man with pronounced anti-contagionist views who first cleared the board by ruling out of consideration all cases in an endemic area, on the grounds that such had no evidential value.

The findings of the Committee were (1) That leprosy is neither syphilis nor tuberculosis but has analogies with the latter (2) That leprosy is not transmitted hereditarily and the disease tends to die out because the majority of lepers are sterile (3) That it is contagious and inoculable but is not spread widely in these ways (4) That leprosy is not peculiar to any race or caste, nor does it arise from the use of any particular food, nor by reason of any climatic or telluric conditions (5) That predisposing causes are poverty, bad food, and insanitation and (6) That it arises *de novo* under a combination of circumstances and conditions whose interrelation is not known.

Consequently, the Commission did not recommend segregation either absolute or partial, but advocated voluntary isolation. Their recommendations included (1) Prohibition of lepers as sellers of food or drink or their engaging in such occupations as barbers and washer men (2) Discouragement of concentration of lepers forbidding vagrant lepers to beg, to use public conveyances or to frequent places of public resort (3) Lepers infringing these regulations were to enter asylums to be built near towns.

Thus we have the peculiar state of things that the disease is contagious to an "exceedingly small" degree but voluntary isolation, prohibition of certain trades and occupations, control of movements and establishment of asylums are recommended for dealing with it. The Government of India adopted the report and on it was based the Leper Act of 1897 which was clearly framed with the view of deferring to public opinion that leprosy is contagious and mitigating a public nuisance. It was a permissive Act enforceable by local governments by notification.

POOTS (Peter) Leprosaria in Mediaeval West Pomerania.—*Internat Jl Leprosy*, Manila, 1939 Apr-June Vol 7 No 2 pp 257-268 With 1 fig

Mediaeval West Pomerania extended from what is now known as the River Ryck near Greifswald to the border of Mecklenburg and included the island of Ruegen. The author speaks of the 13th century onwards and the existence of leprosaria in the towns and countryside of the mainland and on Ruegen. In the earlier days the lepers of a town, excluded from civil and social life, settled outside the city walls and depended for subsistence on charity. Generally they did so well that others joined them till they formed a community and the town council had to provide for their orderly administration. New buildings were erected, usually with a chapel attached and admission depended on payment of a fee but there were funds to pay for the poor. Dr. OBERDORFFER who translated the article from the German studied in Greifswald and knows the district well. He conjectures that the population in the 13th-15th century was not more than 80,000 and nineteen leprosaria are noted and he thinks the incidence was about 5 per mille. In northern Germany states the author it was the custom to dedicate these chapels and leprosaria to St. Juergen (St. George) and wherever he finds a St. Juergen church or village he regards that as evidence of the former existence of a leprosarium. [From records which he has traced of the "leprosaria" becoming transformed into monasteries or almshouses in so short a time as fifty years we can only infer that as elsewhere these houses were not reserved only for lepers but were probably inns for travellers.]

also and that by inference the number of cases in the buildings was not so high as 5 per mille (or 400 interned). The latter figure if correct would lead us to expect at least twice that number in all a 10 per mille incidence clearing up in less than a century. We may call to mind in this connexion Sir W P MACARTHUR's words in his Notes on Old time Leprosy in England and Ireland. The mere label leper hospital attached to an institution is no proof that it ever contained a single leper. The Erse word for oratories he states was translated into Latin as *nosocomia* that is hospitals and on this being rendered into English the gloss leper houses was added so that leper houses became as numerous as oratories.] H H S

BRITISH EMPIRE LEPROSY RELIEF ASSOCIATION *Leprosy, a Key Disease Report for 1938—36 pp With 9 figs & 2 maps London 115 Baker Street W 1*

This report reveals steady progress. It deals with the medical secretary's tour in East Africa and gives summaries of the work in other areas. The Association now employs 18 T. H. lay workers in addition to a few medical men and nurses. A noteworthy feature is the receipt of £8,920 18s 9d from the first wireless appeal. The leprosy exhibition has continued to arouse fresh interest and to obtain increased support wherever it has gone. L Rogers

LOVE (John) *Lecture Notes on Leprosy—56 pp With 14 plates & 2 maps. 1938 New Delhi British Empire Leprosy Relief Association Indian Council, Talkotara Road.*

This booklet consists of lecture notes used by the author in India for addresses. It should be useful to lay workers and beginners.

LOWE (John) & CHATTERJI (S N) *Seasonal Variations in Leprosy in Calcutta.—Internal Jl Leprosy Manila 1939 Apr-June Vol 7 No 2. pp 137-148 With 5 figs*

A visit of Dr OBERDÖRFFER to Calcutta led these authors to study the seasonal activity of their cases as shown by clinical signs and bacteriological findings. An analysis of 2 779 cases seen within three years showed the highest numbers between March and October affecting the neuromacular cases but not the lepromatous ones. Clinical activity was greatest in March to September and the proportion showing bacilli rose markedly to a maximum of 23 per cent. in April and May but fell suddenly in June to below 5 per cent. with a yearly average of below 10 per cent. This indicates an increase of the bacilli early in the year followed by increased cellular activity with a sudden June fall in the bacilli and a later one in cellular activity. Neither STEIN's explanation of sudden meteorological changes nor Oberdörffler's coco-yam hypothesis [see below p 1021] explains these facts which appear to be related to increased bacterial activity in the hot season, ending abruptly with the onset of the rains in Calcutta in June. DECOITTE (J) Contribution à l'étude épidémiologique de la lèpre dans la région du Nepoko (Kibali-Ituri) [Epidemiology in the Nepoko Region.]—*Ann Soc Belge de Méd Trop* 1939 Mar 31 Vol 19 No 1 pp. 1-12. With 1 map

This is a study of leprosy in a badly infected area of the Congo with heavy rainfall. An examination of 8,294 of the native population revealed 388 definite and 162 suspected leprosy cases, 44.37 and 19.53 per mille respectively. This very high rate was favoured by deficient sanitation and infections through prolonged contact especially with cutaneous cases. Males were most affected and a large proportion of the cases were neural. L. R.

COURTNEY (Kenneth O) Leprosy in Panama. A Study of Its Origin and Spread.—*Internat J Leprosy* Manila 1939 Jan.-Mar Vol 7 No 1 pp. 29-40. With 10 figs.

This paper records the results of an inquiry into the occurrence of leprosy in the Panama Republic beyond the limits of the Canal Zone. The infection by the early Spanish settlers is referred to and details of the present distribution with family trees illustrating infections are then given for each province. Four main towns supplied 40 per cent of the 109 cases in the Palo Seco Colony and records of the deaths of 120 other cases were found. In addition, 7 active and 13 unconfirmed cases were met with, and the active cases amount to 0.28 per mille of the population. A history of contact infection was traced in 74 per cent of the cases in the colony and among new provincial cases, and those visited in hospitals and in their families totalling approximately 118 in all except one prior contact with leprosy was established. The disease appears to be a familial one and the author regards it as due to an inherited predisposition coupled with prolonged intimate contact with the disease. L. R.

KERVINGANT (M) & BARÉ (J) La lèpre en Nouvelle-Calédonie en 1936 [Leprosy in New Caledonia in 1936.]—*Internat J Leprosy* Manila 1939 Apr.-June Vol 7 No. 2 pp. 175-200. With 14 figs.

After references to previous inquiries into the leprosy position in New Caledonia in 1914 and 1924 the authors report on the present more hopeful outlook due to the adoption of modern methods of prophylaxis. In the course of a detailed description of the present incidence of the disease they point out that among the natives the sexes are nearly equally affected and the nerve cases greatly exceed the cutaneous. European male cases number twice as many as females, but this is only in proportion to the numbers of each in the islands. The recognized native cases in 1936 numbered 953 or 31.9 per mille and the additional suspected cases were 316 or 10.5 per mille. The European confirmed cases numbered 128 5.2 per mille and the suspected ones 15 or 0.5 per mille. The authors come to the conclusion that the indigenous cases are stationary in number but the European ones are diminishing.

Of greater interest is the information given regarding the adoption of improved methods of prophylaxis. In 1924 there was a nominal and ineffective isolation of patients in 64 segregation villages with no proper supervision and no treatment. In 1936 there were 10 leper

agricultural colonies with good hygiene social amenities and a dispensary to supply regular treatment for the contagious cases. The closed uninfected patients are free are treated in their own villages and are examined every three months. A good colony type of sanatorium has also been supplied for the European patients. The outlook is thus much more hopeful.

CILENTO (Raphael) Leprosy in Queensland.—*Internat Jl Leprosy* Manila 1939 Apr-June Vol 7 No 2. pp 201-208 With 2 figs (1 map)

This brief paper records the present position of the disease in Queensland. A Health Act of 1937 gave new powers to examine suspects and contacts. An inquiry in a northern area revealed a focus of leprosy of 14 clear and 25 suspected cases and every infected family is now being examined every three months for new cases. Between 1925 and 1938 infections have been found in 58 whites and 71 aboriginals and 126 of whom 88 were males and 38 females, have been admitted to the Pearl Island Lazaret. The number of new detections in the five years to 1935 was more than double those found in any of the six previous five-yearly periods owing to the increased number detected in the coloured people. The more active measures should in time prove of benefit.

L. R

DAVIS (A. P.) Leprosy in Western Australia.—*Internat Jl Leprosy* Manila 1939 Apr-June Vol 7 No 2. pp 209-215 With 1 fig

Leprosy is only found in the northern warmer part of the area where an enquiry into its incidence has been carried out during the last two years by Dr Davis. A spot map shows most cases in the northern hot humid Kimberley division and a smaller number in the North West division. In the former 42 cases were found among 4 001 examined and in the latter 2 among 1 690 persons. The disease is said to have been introduced by indentured labour of the pearling industry. The total number of notifications in the West Kimberley division rose from 2-7 in the years 1908 to 1932 to 41-58 in 1933 to 1936. The serious outbreak thus revealed is said to be now well under control and the new notifications fell to 19 in 1937.

DECOTTE (J) Contribution à l'étude épidémiologique de la lèpre dans la région du Nepoko (Kibali Ituri) [Epidemiology in the Nepoko Region.]—Ann. Soc. Belge de Méd Trop 1939 Mar 31 Vol 19 No 1 pp. 1-12. With 1 map

This is a study of leprosy in a badly infected area of the Congo with heavy rainfall. An examination of 8,294 of the native population revealed 368 definite and 162 suspected leprosy cases, 44.37 and 19.53 per mille respectively. This very high rate was favoured by deficient sanitation and infections through prolonged contact especially with cutaneous cases. Males were most affected and a large proportion of the cases were neural. L 1

COURTNEY (Herbert O) Leprosy in Panama. A Study of its and Spread.—Internat J Leprosy Manila, 1939 Jan Vol 7 No 1 pp. 29-40. With 10 figs.

This paper records the results of an inquiry into the occurrence of leprosy in the Panama Republic beyond the limits of the Canal Zone. The infection by the early Spanish settlers and details of the present distribution with family tree infections are then given for each province. Four main types of infection are described. In the Palo Seco Colony 40 per cent. of the 109 cases in the Palo Seco Colony, the deaths of 120 other cases were found. In addition 13 unconfirmed cases were met with, and the active cases numbered 0.28 per mille of the population. A history of contact was traced in 74 per cent. of the cases in the colony, and in 67 per cent. of the provincial cases and those visited in hospitals amounting to a total of approximately 116 in all except one in which leprosy was established. The disease appears to be endemic and the author regards it as due to an inherited predisposition with prolonged intimate contact with the disease.

HERVIGANY (M) & BURET (J) La lèpre en Nouvelle-Calédonie en 1936 [Leprosy in New Caledonia in 1936.]—Ann. Soc. Belge de Méd Trop 1939 Apr-June Vol 7 No 2 pp. 1-14 figs.

After references to previous inquiries into the disease in New Caledonia in 1914 and 1924 the authors record a more hopeful outlook due to the adoption of prophylaxis. In the course of a detailed description of the incidence of the disease they point out that amboyeses are nearly equally affected and the nerve and cutaneous. European male cases numbered 1.5 per mille, but this is only in proportion to the number of males. The recognized native cases in 1936 numbered 0.5 per mille and the additional suspected cases were 0.5 per mille. The European confirmed cases numbered 1.5 per mille and the suspected ones 1.5 or 0.5 per mille. The conclusion is that the indigenous cases are stable but the European ones are diminishing.

Of greater interest is the information given regarding improved methods of prophylaxis. In 1924 there was no isolation of patients in 64 segregation camps, proper supervision and no treatment. In 1936 the

BERTRAND (Ivan) BABLET (Jean) & BLOCK (Françoise) Sur l'inoculation intracérébrale au lapin de bacilles acido-résistants isolés chez les lépreux. [Intracellular Inoculation of Bacilli from Lepers]—*C R Soc Biol* 1939 Vol 130 No 14 pp. 1565-1566

This is a report on the results of intracerebral inoculation in rabbits with acid fast bacilli obtained from leprosy patients. The strain isolated by CHAUSSINAND at Saigon that of LEVI of HYOGO and UCHIDA in Tokyo and of KEDROWSKY have been used by the technique the authors had previously employed in the case of tubercle and paratubercle bacilli. The first three forms gave negative results but Kedrowsky's bacillus produced similar lesions to those caused by paratubercle bacilli so the authors conclude that this organism is a bovine tubercle bacillus isolated from a leprosy patient infected by both it and the true lepra bacillus. - i. TISSEUIL (J) Essai d'inoculation de la lèpre humaine aux lépreux par greffe hétéroplastique dermo-épidermique [Inoculations of Human Leprosy Bacilli into Animals.]—*Bull Soc Path Exot* 1939 Apr 4 Vol 32. No 4 pp 382-385
- ii. — Essais d'inoculation de la lèpre humaine au rat d'élevage. (Première note)—*Ibid* pp 542-545
- iii. — Essais d'inoculation de la lèpre humaine au rat d'élevage. (Deuxième note)—*Ibid* pp 546-553

These papers report further attempts by the author to infect animals with human lepra bacilli. This is a record of further grafting of tuberculoid leprosy infected skin into other infected subjects who are more likely to give positive results than apparently healthy subjects. In two instances at the end of four to six months new tuberculoid leprosy lesions were found. In a third lepra bacilli were still found in the lesions at the edge of the ulcer.

ii. This note records attempts to inoculate human leprosy into bred rats. Emulsions of leprosy material were used, with the addition of biological or chemical substances or other acid fast bacilli. With emulsions the local reaction quickly disappeared. With the addition of other substances reactions of variable strength resulted and in two a second injection after 6 to 8 weeks produced a black slough. The glands were frequently positive for acid fast organisms after four months. No results were obtained by ingestion of the leprosy material, so the results were all negative as far as reproducing human leprosy lesions is concerned.

iii. In this series of experiments the emulsions of leprosy material were made up in broth, beef bile, gelatine, olive oil, glycerine and vaseline respectively as culture media favourable to bacillary growth and other acid fast bacilli were added in some. No definite results were obtained. L. R.

SUZUKI (Rissyun) Ueber die Impfung von Tieren mit Leprabazillen. [Inoculation of Animals with Lepra Bacilli.]—*Tohoku Ji Experim Med* 1939 July 30 Vol. 36. Nos. 2 & 3 pp 146-152. With 3 figs. (2 coloured)

This short paper records that intraperitoneal injection of lepra bacilli resulted in the formation of nodules containing the organisms which are believed to have increased in numbers. L. R.

IANES (James Ross) Report of Leprosy Survey of the British Solomon Islands Protectorate.—70 pp. With 9 maps (3 folding) 1 plan & 1 diagram. 1938 Suva, Fiji.

This is the full report of the inquiry a summary of which was dealt with in this *Bulletin* 1938 Vol 35 p 882. It brings out the laborious nature of the survey and takes a fairly hopeful view of an attempt to control the disease by the colony system with outlying dispensaries, as in use at Uruakoh in Nigeria, while not minimizing the difficulties owing to the bush nature of the most heavily infected island of Malaita.

L. R.

MIR (Ernest) Leprosy in Africa.—*Trans Roy Soc Trop Med & Hyg* 1939 June 29 Vol 33 No. 1 pp 119-126

This address is of a general nature. The author once more considers leprosy to be a disease that especially attacks primitive people on coming into social and industrial communication with more civilized races including changes of diet clothing and manner of life. A table is given of the estimated number of leprosy cases in British African possessions which total 256,000 and is considered to be below the truth. The method of prophylaxis in use in South Africa is a modified form of compulsion and in Nigeria is a free colony system with outlying treatment dispensaries with the sympathetic help of missionaries and T. O. C. H. workers.

RYER (G. A.) Some Principles for directing Leprosy Surveys.—*Jl Malaya Branch Brit Med Assoc* 1939 Mar Vol. 2. No. 4 pp 233-238

This brief note is largely concerned with the local conditions necessitating patience and tact in Malaya during leprosy surveys. A card is described for recording the observations. The author emphasizes that a great deal can be done by treatment especially in tuberculous leprosy. Attention should be paid to diet in relation to incidence. A leprosy mobile unit is advised for survey propaganda and treatment similar to that long used in India. A large factor in concealment of cases is the "bugbear of compulsory institutionalism." A full list of all known patients should form the basis of the survey.

L. R.

BERTRAND (Ivan) BABLET (Jean) & BLOCK (Françoise) Sur l'inoculation intracérébrale au lapin de bacilles acido-résistants isolés chez les lépreux. [Intracellular Inoculation of Bacilli from Lepers.]—*C R Soc Biol* 1939 Vol. 130 No 14 pp 1565-1566

This is a report on the results of intracerebral inoculation in rabbits with acid fast bacilli obtained from leprosy patients. The strain isolated by CHAUSSINAND at Saigon that of LEVY of HYOGO and UCHIDA in Tokyo and of KEDROWSKI have been used by the technique the authors had previously employed in the case of tubercle and paratubercle bacilli. The first three forms gave negative results but Kedrowski's bacillus produced similar lesions to those caused by paratubercle bacilli so the authors conclude that this organism is a bovine tubercle bacillus isolated from a leprosy patient infected by both it and the true lepra bacillus.

McKINLEY (Earl B.) The Bacteriology of Leprosy A Review —
Internat. Jl Leprosy Manila. 1939 Jan-Mar & Apr-June.
Vol. 7 Nos 1 & 2. pp. 1-28 217-255 [296 refs.]

This article is indeed an excellent review of a subject which has presented many difficulties and problems to which many research workers of renown have devoted much time in solving since HANSEN's momentous discovery in 1874. The author considers the subject in a critical manner from the early studies of GAUCHER, THIM STEVEN LUTZ and RAKE, who all attempted cultivation of the organism associated with lepra lesions on the various media known in their day but were unable to obtain confirmatory results by animal inoculation. The author proceeds to describe the measures tried under periods, 1890-97 which includes the work of HANSEN KANTHACK, BARCLAY DUCKEY BYRON ROCCA and UHNA 1897-1900 with the studies of LEVY SPROCK, Czaplewski MAL TEICH SCHOLTZ and KLINGMULLER 1900-1909 mainly dealing with KEDROWSKI's work and that of ROST WEIL and WHERRY who confirmed the pleomorphism of cultures which others had also observed 1909-12 and the Philippine investigators notably CLEGG and the symbiotic cultivation in association with an amoeba, confirmed by CURRIE, BRUCKERHOFF and HOLLMANN and the work of TEAGUE, DUVAL, SERA, BAYON and others 1913-17 the chief investigators of this period being FRASER, FLETCHER, REENSTIERNA, MCCOY and again ROST.

The question at that time may be summed up by saying that none of these organisms had established the claim to be the *true leprosy organism*. The author next considers in fuller detail the claims of Walker's diphtheroid types, the partly acid-fast organisms of Bordoni-Uffreduzzi and others, of de Souza Aranzo of Shiga the rat-leprosy studies and finally his own investigations with Soule. He describes his technique and the animal experiments carried out by himself and his colleague and concludes. There seems to be no good reason to question the status of that organism [Hansen's bacillus] which is so constantly associated with lesions of this disease. Its final cultivation on artificial media will one day be accepted another chapter in the study of this disease will be brought to a close and new vistas of study will be opened.

[It is not possible to abstract this valuable article by Dr McKinley it is itself a review crammed full of interesting points. The following quotation from SCOTT a recently published *History of Tropical Medicine* calls attention to further work on cultivation of the organism of leprosy not included in the article above. He states (p 629)

Throughout 1838 attempts were made at the Calcutta School of Tropical Medicine to confirm the reports of successful cultivation. Twenty four series of experiments were carried out and a thousand tubes of different media inoculated. Of seventy tubes seeded in August and kept in a gaseous environment of 40 per cent. oxygen and 10 per cent. carbon dioxide thirty five showed slight macroscopic and considerable microscopic evidence of colony formation and many masses of acid-fast bacilli were seen in smears. Of another seventy under ordinary atmospheric conditions fourteen showed similar but less evident growth.

On the same page referring to McKinley's own work.

By 1937 McKinley and de Leon reported having earned the cultivation through sixty generations. The most successful medium has proved to be hormone-glycerol-agar.]

SUWO (Masasue) & KIN (Shotai) Ueber kulturen von leprösen gewebe in vitro I Mitteilung Gewebskulturen von haut knötchen bei menschenlepra. [Tissue Culture of Human Leprosy Nodules].—*Internat J Leprosy* Manila. 1939 Jan.-Mar Vol 7 No 1 pp 57-66 With 21 figs. on 4 plates [10 refs.]

Bacillus-containing leprosy tissues have been studied in cultures. It was found that small pieces of leprosy nodules grow well in tissue culture with fibroblasts and epitheloid cells with lepra bacilli in them the latter appear to accumulate in the fibroblasts and lepra cells develop from the epitheloid cells with multiplication of bacilli in them and in the fluid, but without visible colonies of the organisms

McKINLEY (Earl B.) The Bacteriology of Leprosy A Review —
Internal. J. Leprosy Manila. 1939 Jan.-Mar & Apr-June.
 Vol. 7 Nos 1 & 2 pp 1-28 217-255 [296 refs.]

This article is indeed an excellent review of a subject which has presented many difficulties and problems to which many research workers of renown have devoted much time in solving since HANSEN's momentous discovery in 1874. The author considers the subject in a critical manner from the early studies of GAUCHER, THIN, STEVEN, LUTZ and RAKE who all attempted cultivation of the organism associated with *lepra leprosa*, on the various media known in their day but were unable to obtain confirmatory results by animal inoculation. The author proceeds to describe the measures tried under periods, 1880-87 which includes the work of HANSEN, KASTHACK, BARCLAY, DUCREY, BYRON, ROCCA and UANA. 1897-1900 with the studies of LEVY, SPRONCK, CZAPLEWSKI, MAX, TEICH, SCHOLTZ and KLINGMULLER. 1900-1909 mainly dealing with KEDROWSKI's work and that of ROST, WEIL and WHEERRY who confirmed the pleomorphism of cultures which others had also observed. 1909-12 and the Philippine investigators, notably CLEGG and the symbiotic cultivation in association with an amoeba, confirmed by CURRIE, BRINCKERHOFF and HOLLMANN and the work of TEAGUE, DUTAL, SERRA, BAYON and others. 1913-17 the chief investigators of this period being FRASER, FLETCHER, REED, STIERNA, MCCOT and again ROST.

The question at that time may be summed up by saying that none of these organisms had established the claim to be the *true leprosy organism*. The author next considers in fuller detail the claims of Walker's diphtheroid types, the partly acid-fast organisms of Bordoni-Uffreduzzi and others, of de Souza Araujo of Shiga, the rat leprosy studies and finally his own investigations with Soule. He describes his technique and the animal experiments carried out by himself and his colleague and concludes: "There seems to be no good reason to question the status of that organism [Hansen's bacillus], which is so constantly associated with lesions of this disease. Its final cultivation on artificial media will one day be accepted, another chapter in the study of this disease will be brought to a close and new vistas of study will be opened."

[It is not possible to abstract this valuable article by Dr McKinley, it is itself a review crammed full of interesting points. The following quotation from SCOTT's recently published *History of Tropical Medicine* calls attention to further work on cultivation of the organism of leprosy, not included in the article above. He states (p. 829):

Throughout 1896 attempts were made at the Calcutta School of Tropical Medicine to confirm the reports of successful cultivation. Twenty-four series of experiments were carried out and a thousand tubes of different media inoculated. Of seventy tubes seeded in August and kept in a gaseous environment of 40 per cent oxygen and 10 per cent carbon dioxide thirty-five showed slight macroscopic and considerable microscopic evidence of colony formation and many masses of acid-fast bacilli were seen in smears. Of another seventy under ordinary atmospheric conditions fourteen showed similar but less evident growth."

On the same page referring to McKinley's own work.

By 1937 McKinley and de Leon reported having carried the cultivation through sixty generations. The most successful medium has proved to be hormone-glycerol-agar."

RADNA (R.) Sur la bacillurie des lépreux. [Bacilluria in Leprosy]—*Ann Soc Belge de Méd Trop* 1939 Mar 31 Vol 19 No 1 pp 51-53

The elimination of lepra bacilli in the urine has been studied in view of the finding of BERNY that the organisms of rat leprosy are more frequently eliminated in animals undergoing arsenical treatment. Repeated examination of the urine of patients before the administration of arsenic always proved negative but in 9 cases being treated with

urine in the form of novarsenobenzol for complicating syphilis or lepra, the urine was commonly positive for lepra bacilli in lepromatous, but not in nerve cases. Such cases should therefore be treated in hospitals when possible. L. R.

RADNA (R) Contribution au problème de la transmission de la lèpre Les formes de la lèpre dans la région de Pawa et leur infectiosité Première note l'élimination du bacille de la lèpre. [Transmission of Leprosy The Elimination of the Bacilli.]—*Ann Soc. Belge de Méd. Trop.* 1939 Mar 31 Vol. 19 No. 1 pp 39-50

This inquiry into the modes of transmission of leprosy is in agreement with the general view of the importance of the discharge of lepra bacilli from the nose and skin. Droplet infection in laryngeal cases and the escape of lepra bacilli through the genito-urinary apparatus, in the milk, tears and stools are also considered to be possible means of infection. L. R.

RADNA (R) Contribution au problème de la transmission de la lèpre Les formes de la lèpre dans la région de Pawa et leur infectiosité. Deuxième note la transmission du bacille de Hansen. [Transmission of Leprosy]—*Ann Soc. Belge de Méd. Trop.* 1939 June 30, Vol 19 No 2 pp 201-224 With 1 graph. [13 refs.]

This is an epidemiological study of the conditions of leprosy infections in a French colony. An attempt was made to discover the sources of infection in 241 cases of leprosy by house inquiries with success in only 132, in 125 of which the transmission occurred in the family. The possibility of hereditary transmission was considered, with the conclusion that although it could not be denied, at the most it could play very little part. Contact infection is then dealt with and the dangers of contamination by dust of rooms and through smoking pipes and cigarettes is pointed out. Infection through bedbugs, flies and other insects is considered to be possible but rare. The general conclusion is that family contact constitutes the greatest danger. L. R.

LEISHMANIASIS

PRELIS OF ABSTRACTS IN THIS SECTION

ZAMBRANO (p. 1024) adds physiological saline or skimmed goats milk to the water of condensation of NNN medium for the cultivation of leishmania. SEXEKI (p. 1024) describes the preparation of a medium more suitable than NNN for the primary isolation of *L. tropica*.

ADLER and THEODOR (p. 1025) studied the development of *L. chagasi* in *P. papatasi* which had been infected by feeding through a membrane upon a suspension of flagellates. Passage of flagellates to the oesophagus may occur as early as 3 days after feeding.

CHUNG and FENG (p. 1025) found flagellates indistinguishable from developing leishmania in *P. chinensis*. They (p. 1025) show that *P. chinensis* is a satisfactory host for the parasite of canine kala azar in Peiping and consider that this fact may throw light on the epidemiology of human disease if the parasites are identical.

GIRAUD *et al* (p 1026) restate the theory that in Marseilles kala azar is primarily a disease of dogs and that it is transmitted to children by the dog tick. SERGENT *et al* (p 1026) also believe that Mediterranean kala azar is mainly a disease of dogs and that transmission is from dog to dog and from dog to child rather than from child to child. They therefore advise control of dogs and prevention of contact but they incriminate sandflies dog ticks not being mentioned

DA CUNHA (p 1027) shows that in the skin of dogs infected with S. American kala azar there are collections of macrophages containing parasites. The skin may otherwise appear to be normal. He considers that this parasite is identical with *L. infantum*

FENG *et al* (p 1027) describe the symptoms in 12 dogs suffering from kala azar in Peiping and Ho (p 1027) notes that there was a child with kala azar associated with one of these dogs.

MENDES (p 1028) records canine kala azar in Lisbon

PAPANTOYAKIS (p 1028) describes the measures taken in Canea to prevent the spread of canine kala azar and its transmission to man. All dogs are carefully examined and the destruction of infected dogs has been followed by reduction in the number of human cases

BLANC (p 1028) found a squirrel dead of leishmania infection in Morocco

MURANO and VECCHIO (p 1029) consider the anaemia of kala azar to be due to alterations in the reticulo-endothelial system brought about by the leishmania

MENON (p 1029) discusses the splenic reaction in kala azar which at first is a reticulo-endotheliosis. DE VRIES (p 1029) regards a positive formol-gel reaction as merely an indication of hyperglobulinaemia.

GREVAL *et al* (p 1030) quote figures to show the value of complement fixation tests with a certain technique using the W.K.K. antigen

NAPIER (p. 1030) though regarding sternal puncture as a valuable aid to diagnosis obtains better results from splenic puncture which in his hands has not proved harmful.

An incubation period of 1-2 years was a feature of a case reported by PALLISTER (p. 1030). Two cases of kala azar from the South of France are reported by OLMER *et al* (p 1030). LEAHY (p 1031) reports kala azar probably contracted in Sicily in a child in the United States. SHAPIRO and BIESH (p 1031) describe a child in Palestine with kala azar and leishmaniasis of the face. DASTIDAR (p 1031) describes post kala azar dermal leishmaniasis in an Indian. Leishmania were found in nodules on the tongue. LINTON (p 1031) describes kala azar in a Lascar seaman in Glasgow. GATTI *et al* (p 1032) describe kala azar in a Paraguayan apparently contracted in Bolivia.

FERRABOUX *et al* (p 1032) describe clinical cases in one of which the early stages were afebrile with consequent delay in diagnosis

ERMEN (p 1032) shows that neostibosan produces histiocyte response and leucocytosis in hamsters but found a leucopenia. WANG (p 1032) found a higher rate of cure in infected hamsters with neostibosan than with solustibosan. Daily injections are less effective with both than bi weekly or tri weekly injections

AVERSA (p 1033) speaks well of solustibosan in infantile kala azar. MIRZOJAN (p. 1033) reports on the value of sourmine (stibosan) in treatment. DAS GUPTA (p 1033) shows that allergic symptoms after intravenous ureastibamine, once common have not often been seen since smaller (but still efficacious) dosage was adopted.

POGGI and MOVITI (p 1033) show that oriental sore is common in the province of Forlì, Italy. VANNI (p 1034) incriminates *P. macdonaldi* as the intermediate host of *L. tropica* in Abruzzi.

JERACE (p 1034) shows that in Teramo (Italy) the distribution of *P. perfoliatus* corresponds with that of cutaneous leishmaniasis. BERBERIAN (p. 1034) has succeeded in effecting further transmissions of oriental sore by allowing *Stomoxys calcitrans* to bite volunteers immediately after feeding on a sore. He (p 1035) succeeded in infecting 35 volunteers with *L. tropica* from cultures and considers this procedure to be useful in conferring immunity.

PELLETTIERI (p 1035) reports oriental sore in a patient from Eritrea. DA CUNHA and DIAS (p. 1035) use an antigen prepared from strains of leishmania isolated from S. American cutaneous leishmaniasis.

PIFANO (p 1035) finds formalin to be the treatment of choice for mucocutaneous leishmaniasis in the Argentine.

WEINMAN (p 1036) describes a technique for the cultivation of *L. tropica* in pieces of guinea pig tissue on the surface of blood or serum-Tyrodé agar. C II

ZAMBRAO (Ebo) *Cultivabilità del parassita di Leishman su terreno NVN con aggiunta di soluzione fisiologica clorodidica* [Cultivability of the Leishmania Parasite on NVN Medium with Added Physiological Saline Solution].—*Giorn. di Bacteriol e Immunol* 1939 June Vol 22 No. 6 pp. 881-890 [10 refs.] English summary (9 lines)

The author shows that leishmania can be successfully cultured and subcultured in NVN medium in which the water of condensation has been replaced or increased by the addition of physiological saline solution. Before inoculation the liquid is allowed to remain in contact with the surface of the blood agar for 24 hours in the incubator at 37°C. Equally good results are obtained by the similar use of skimmed goats milk. C M Wenyon

SENEKJI (H. A.) *Studies on the Culture of Leishmania tropica*—*Trans. Roy. Soc. Trop. Med. & Hyg.* 1939 July 23 Vol. 33 No. 2 pp. 267-269

The author has found that ordinary NVN medium does not give very satisfactory results for the primary isolation of *Leishmania tropica* from oriental sores. A better medium is prepared as follows. To 50 grammes of Bacto beef, 1000 cc. of distilled water is added. The mixture is infused for one hour at 60°C. and then heated for five minutes at 80°C. to coagulate some of the protein. After keeping in the ice-chest for 24 hours the mixture is filtered. To the filtrate are then added neopeptone (Difco) 20 grammes, sodium chloride 5 grammes, agar (Nobel) 20 grammes. When solution has taken place by heating, the pH is adjusted to 7.2 to 7.4 and 1.5 cc. amounts are distributed in test tubes and 30 cc. amounts in Blake bottles with screw caps. After the tubes and bottles have been sterilized in the autoclave they are cooled to 55°C., at which temperature defibrinated rabbit blood is added to an amount equal to 15 per cent. of the medium. After gently mixing the contents, the tubes and bottles are sloped. Primary cultures are readily obtained in the water of condensation

of the tubes By inoculating the water of condensation in the bottles with cultures and allowing the water to flood the agar surface cultures are obtained

ADLER (S) & THEODOR (O) The Behaviour of *Leishmania chagasi* in *Phlebotomus papatasi*—*Ann Trop Med & Parasit* 1939 Mar 31 Vol 33 No 1 pp 45-47

The authors have already described a method for inducing sandflies to feed through a membrane on suspensions of leishmania flagellates. In the case of *Phlebotomus papatasi* the flies feed with reluctance unless the fluid contains red blood corpuscles. If however the membrane is smeared with a solution of cane sugar as many as 80 per cent of the flies will feed. The relative infectivity of different flies can be tested by allowing them to ingest emulsions of known flagellate content. Generally, it is found that the percentage of flies becoming infected increases with the increase in the flagellate content of the emulsion. Thus of flies fed on emulsions of *Leishmania chagasi* containing 300 flagellates per 0.1 cmm. 24 per cent became infected, while of those fed on emulsions containing 1,000-2,000 per 0.1 cmm. 71 per cent were infected while with still higher concentrations the figure was 89 per cent. When an infection has been established in the flies the flagellates multiply in the midgut and ascend to the anterior part of the cardia which may become choked with flagellates. Passage into the oesophagus may occur as early as three days after feeding. In its behaviour in *P. papatasi* *L. chagasi* resembles *L. donovani* and *L. infantum* since both these give a low infection rate in flies fed on emulsions containing 300-400 flagellates per 0.1 cmm. of emulsion

CHUNG (Huei Lan) & FENG (Lan-Chou) Natural Infection of *Phlebotomus chinensis* in Peiping with *Leishmania* Flagellates.—*Chinese Med J* 1939 July Vol. 56. No 1 pp 47-51
With 1 plate

In the kennel of a dog suffering from canine kala azar and in the house of the owner in Peiping, 16 specimens of *Phlebotomus chinensis* were captured between the 5th and 10th June 1939. Of these flies two were found to be infected with flagellates indistinguishable from developmental forms of leishmania.
C M W

FENG (Lan-Chou) & CHUNG (Huei Lan) The Development of *Leishmania* in Chinese Sandflies fed on Dogs with Canine Leishmaniasis.—*Chinese Med J* 1939 July Vol. 56. No 1 pp. 35-46
With 5 figs. on 2 plates. [12 refs.]

The authors in Peiping N China have fed sandflies on dogs naturally or experimentally infected with canine leishmaniasis. Two species of sandfly were used, *Phlebotomus sergenti* var *mongolensis* and *P. chinensis*. Both became infected with flagellates but the latter more readily than the former which lost its infection when the blood meal was completely digested. In *P. chinensis* the infection persisted and extended forwards to the pharynx and proboscis a feature which was not observed in the transitory infection in *P. sergenti*. In the case of both sandflies flagellates were found in the hind gut while

they were seen in faeces deposited by one *P. chinensis*. The rate of infection of the sandflies was directly proportional to the degree of infection of the skin of the dogs. One dog with a heavy skin infection led to the infection of the majority of both species of sandfly fed on it. The results with the canine disease agree fairly closely with those previously obtained in the case of human kala azar by YOUNG and HERTIG 1928 PATTON and HINDLE 1927 HINDLE 1928 and WU and SUN 1938 who concluded that *P. chinensis* was the host for the parasite of human kala azar. The present finding that this sandfly is a satisfactory host for the parasite of canine kala azar affords an explanation of the frequent occurrence of the canine disease in Peiping and may also throw light on the epidemiology of human kala azar should it be proved that the human and canine diseases in China are identical. [See also this *Bulletin* 1927 Vol. 24 pp 183 639 1929 Vol. 28 p. 311 1938 Vol. 35 pp 861 862] C M IV

- GIRAUD (Paul) & BERGIER (Pierre) *Epidémiologie de la leishmaniose humaine à Marseille.* [Epidemiology of Human Kala Azar in Marseilles.]—*Bull et Mém Soc Méd Hôp de Paris* 1899 Apr 10. 55th Year 3rd Ser No 12 588-591 With 1 chart
 — & — Recherches sur le mode de transmission de la leishmaniose dans la région marseillaise [Mode of Transmission of Kala Azar in the Marseilles Region.]—*Ibid* pp 591-593
 — CABASSU (H.) & BERGIER (Pierre) Recherches sur l'endémie de leishmaniose canine à Marseille. [Endemic Canine Kala Azar in Marseilles.]—*Ibid* pp 594-596. With 1 chart.

In these three papers the epidemiology of kala azar in Marseilles is discussed. In human beings the disease most commonly attacks children between the ages of one and three. By far the greater proportion of cases comes from the districts round Marseilles itself or from houses in the suburbs where there are gardens. Canine kala azar is also common and is found chiefly in the same districts as the human cases. The conclusion is that kala azar is essentially a canine disease which passes to human beings accidentally. Of vectors the authors suspect the dog tick which is found in greatest numbers on the types of dog most subject to kala azar namely hunting dogs and police dogs. The dog tick bites children which play about on the ground and come into closer contact with dogs than do adults amongst whom the disease is rarely found. The sandfly bites adults as frequently as children, and dogs less often. One case is mentioned in which a child suffered from the tick-borne *fièvre boutonneuse* in September and kala azar in November of the same year. The question is asked was this an instance of simultaneous inoculation of two viruses? The possibility of the dog louse (*Linognathus pulicis*) being a vector is put aside in spite of the fact that Professor JOYEUX is stated to have shown that leishmania will develop in it. C M IV

- SERGEANT (Edm.) PARROT (L.) DOXATIEU (A.) & LESTOQUARD (F.) *La prophylaxie de la leishmaniose générale méditerranéenne.* [Prophylaxis of Mediterranean Kala Azar.]—*Arch. Inst. Pasteur d'Algérie* 1899 June Vol 17 No. 2 pp. 221-230.

The paper discusses the prophylaxis of Mediterranean kala azar, which occurs in human beings and dogs and appears to be transmitted by sandflies, chiefly *Phlebotomus perniciosus* from dog to dog and

from dog to human being rather than from one human being to another. In practically all centres of the disease there are more cases amongst dogs than human beings while sandflies are much more readily infected by feeding on dogs owing to the tendency in these animals for the parasites to be present in large numbers in the skin [see DA CUNHA below]. It has been found that reduction in the human reservoir by treatment of all cases has not been followed by a lowered incidence of the disease. As the disease mostly affects children contact of these with dogs should be prevented. All known infected dogs and all stray unowned dogs should be destroyed. The movement of dogs into and from known centres of the disease should be forbidden it being borne in mind that many dogs harbour parasites without showing any signs of their infection. As regards sandflies protection from bites can be largely effected by the use of a sufficiently fine net at nights while destruction of flies in the rooms can be carried out. Breeding can be prevented to some extent by working the land round the house burying accumulations of rubbish and generally keeping the surroundings clean.

DA CUNHA (Aristides Marques) Infecção da pelle na leishmaniose visceral experimental do cão [Condition of the Skin in Dogs experimentally infected with Kala Azar]—*Brasil Médico* 1938 Nov 26 Vol. 52, No 48 pp 1071-1072.

A study of the skin of dogs experimentally infected with the leishmania of S American kala azar has shown that as in the case of dogs in the Mediterranean region it becomes infiltrated with macrophages containing parasites. The skin apart from the presence of macrophages may be quite normal and have no visible signs of infection or there may develop areas of tumefaction in which numerous leishmania can be found. The observations like others that have been made before lend support to the view that the parasite of S American visceral leishmaniasis is identical with *Leishmania infantum*.

C M W

FENG (L. C.) CHUNG (H. L.) & HORFFLI (R.) Canine Leishmaniasis with Skin Lesions observed in Peiping—*Chinese Med J* 1939 Apr Vol. 55 No 4 pp 371-382. With 15 figs. on 4 plates.

The paper gives an account of twelve dogs which were found to be suffering from canine leishmaniasis in Peiping. In all cases diagnosis was established by the finding of leishmania in smears from cutaneous lesions. The symptoms in these dogs were seborrhea, scaling and depilation of the skin small nodules ulcerations on various parts of the body but especially on the ears face nose and round the eyes. In two dogs keratitis was noted and marked emaciation in five. The other dogs appeared quite healthy apart from the skin lesions. In none of these cases was examination of the internal organs carried out but there is little doubt that the dogs were suffering from canine kala azar.

Ho (E. A.) A Note on the Coincidence of Human Kala-Azar and Canine Leishmaniasis with Cutaneous Lesions in a Household.—*Chinese Med J* 1939 June Vol. 55 No 6 pp 568-567.

The author notes that one of the twelve dogs reported as suffering from canine leishmaniasis in another paper reviewed here [FENG

CHUNG and HOEPLI above] came from a house in which a case of kala azar in a child $2\frac{1}{2}$ years of age occurred. The dog had commenced to show skin lesions as evidence of its infection about a year before the appearance of the first symptoms in the child. A similar association of canine and infantile kala azar in a house in Peiping has been reported by LEE in 1937

C M W

MENDES (A B Corrêa) Leishmaniose nos cães de Lisboa. [Leishmaniasis in Lisbon Dogs.]—*Arguinos Inst. Bact. Camara Pexiana*. 1938 Vol 7 No 3 pp. 389-395 English summary

In 1911 ALVARES and PERRIRA DA SILVA reported the finding in Lisbon of 13 cases of canine kala azar amongst 418 dogs examined. In the present paper the author records the discovery of leishmania in 5 of 240 dogs examined post-mortem. In all cases but one the presence of parasites was associated with a positive formol-gel reaction but in three cases giving a positive reaction leishmania were not found, though two of these were instances of infection with *Dirofilaria immitis* and one with *Babesia canis*.

C M W

PAPANTOAKIS (Evangelos) Bekämpfungsmassnahmen der kala Azar in Canea/Kreta. [Kala Azar Control Measures in Canea (Crete).]—*Arch f. Schiffs u. Trop Hyg* 1939 June, Vol. 43, No. 6 pp. 273-275 With 1 fig

The close association of human and canine kala azar in Canea in Crete has strengthened the belief that the dog is acting there as the reservoir of infection which is transmitted to human beings by sandflies. The destruction of the majority of the dogs in the district of Canea in 1933 was followed by a markedly lower incidence of human kala azar in the following year. Accordingly regulations were drawn up by the Health Department insisting on an inspection of all dogs of Canea in April of each year. Each dog was examined clinically as well as serologically by the formol-gel test. All sick dogs and those giving a positive test were killed. Furthermore if in any village of the district a case of human kala azar occurs, all the dogs of the village are to be at once destroyed. Anyone who objects to his dog being killed may take it for test to the Hygiene Centre in the town as in the case of the town dogs. The residents of such a purged village can only acquire new dogs in the months of January or February while the animals must be under two months of age and must have come from villages where no cases of the human disease have been reported.

The general inspection of dogs in Canea was first carried out in April 1938. Of 1115 dogs 229 gave a positive formol-gel test. Of these 70 per cent. showed no signs of disease, 25 per cent. merely some wasting and loss of hair and only 5 per cent. the characteristic signs of canine kala azar

BLANC (G) Leishmaniose viscérale généralisée observée chez un écureuil (*Verus getulus* L.) au Maroc. [Generalized Kala Azar in a Squirrel (*Verus getulus*) in Morocco.]—*Bull. Soc. Path. Exot.* 1939 July 12, Vol. 32, No. 7 pp. 756-781 With 2 plates. [12 refs.]

Among a number of squirrels (*Verus getulus*) bred at the Pasteur Institute in Morocco one was discovered to have died of a very intense

leishmania infection. The origin of the infection could not be traced as no animals with this infection had been housed in the building for some time. It is admitted that dogs and possibly other animals may harbour leishmania though they appear quite healthy. Furthermore it was not possible to identify the species of parasite as the infection was not transmissible to other animals owing to the decomposed state of the body of the squirrel. The possibility of this animal being a reservoir for leishmania infection is discussed though it is admitted that the only conclusion that can be drawn from the facts is that it is susceptible to infection. C M W

MURANO (Giulio) & VECCHIO (Federico). Sull'interessamento del sistema reticolo-istiocitario nella leishmaniosi interna. I. L'anemia da leishmaniosi interna. [Relation of the Reticulo-Endothelial System to Kala Azar. I. The Anaemia of Kala Azar].—*Pediatrics* 1939 July, Vol. 47 No 7 pp 545-563 [43 refs.]

An examination of the blood of a number of cases of infantile kala azar in Naples and the study of rabbits by blockages of the reticulo-endothelial system has led the authors to the view that the anaemia of kala azar cannot be attributed to any haemolytic process. It is due rather to a hyperplasia of the bone marrow caused by alterations in the reticulo-endothelial system brought about by the leishmania. C M W

MENON (T. Bhaskara). The Splenic Reaction in Kala-Azar.—*Trans Roy Soc Trop Med & Hyg* 1939 June 29 Vol. 33 No 1 pp 75-86 With 8 figs. on 4 plates. [47 refs.]

This study, based on material from ten fatal cases of kala azar has shown that the disease is a reticulo-endotheliosis caused by a parasitic invasion of the cytoplasmic reticular syncytium. There is a gradual differentiation of the reticulo-endothelial tissue to form free histiocytes which are also parasitized. The splenic reaction affords suggestive evidence for the presence in the spleen of two types of phagocytic cell with differing powers of phagocytosis. In the later stages there is a spread of infection to the lymphatic reticulum of the spleen. Such an activation and invasion of the lymphatic reticulum is offered as the explanation of the involvement of the lymphatic tissue in the disease. Reticulo-endothelial blockage is regarded as the probable cause of the anaemia and tendency to inflammatory complications. C M W

DE VRIES (A). On the Connection between the Formol-gel Reaction and the Blood Proteins.—*Acta Med Scandinavica* 1939 Vol 89 No 5 pp 425-434 With 1 graph. [11 refs.]

In this paper the author gives an account of his examination of the serum from a large number of different diseases. He has found that whenever the total globulin content reached 37 parts per thousand the formol-gel reaction was positive while it was uniformly negative when the value fell to below 36 parts per thousand. Between 36 and 37 the reaction was either positive or negative. A decrease in the albumin content had little influence on the reaction. It is clear

- GATTI (C.) BOGGINO (J) & PRIETO (C) Un nouveau foyer de leishmaniose viscérale en Amérique du Sud. [A New Focus of Kala Azar in S. America.]—*Bull. Soc. Path. Exot.* 1939 June 14 Vol 32 No 6 pp 602-605 With 1 fig

The paper describes a case of kala azar in an adult Paraguayan. Though he had travelled, a residence of a year in Yungas in the north of Bolivia before the first symptoms of infection developed appears to indicate that this district must be added to those already recognized as centres of the disease in South America. The other centres are those of Matto Grosso on the borders of Brazil and Paraguay those of Salta and Chaco in Northern Argentina and that of North-Eastern Brazil, south and east of Para. C M W

- FERRABOLI (L.) JAUMES (C) & JUDE (A) Remarques cliniques sur deux cas de kala azar [Clinical Observations on Two Cases of Kala Azar]—*Rev. Méd. et Hyg. Trop.* 1939 Mar-Apr Vol 31 No 2 pp 58-61

Two cases of kala azar are described in adults who had returned to France from Morocco and French Somaliland. It seems probable though not quite certain, that the infections had been contracted in these countries. In one case the diagnosis was difficult owing to the main symptoms resembling those of acute peritonitis. In the other the early stages of the disease were afebrile the patient being admitted to hospital for general debility combined with enlargement of the liver and spleen. A diagnosis of curthosis was made. It was not till six months later that the first febrile symptoms developed. The first case was much more resistant to antimony treatment than the second several courses of large dose being required to bring about a cure. C M W

- ERMEN (Johannes) Die Wirkung von 3- und 5wertigem Antimon auf das weisse Blutbild bei gesunden und mit kala-azar infizierten Hamstern [The Influence of Tri and Pentavalent Antimonials on the Leucocytes of the Blood in Healthy and Kala Azar Infected Hamsters.]—*Ztschr. f. Immunopath. u. Experim. Therap.* 1938, July 8 Vol 83 No 3/4 pp 209-228. With 5 figs. & 7 charts [22 refs]

This paper has already been the subject of a review [this *Bulletin* 1938, Vol 35 p 870] but it was there erroneously stated that a leucocytosis followed the administration of fousadin to healthy hamsters, whereas the reverse is the case. It thus appears that neostibosan administered to hamsters produces a marked histocyte response as well as an increase in the number of leucocytes an action which is related to the therapeutic efficiency of the drug in the treatment of leishmania infections in these animals. Fousadin not effective for treatment produces only a very slight histocyte response and a decrease in the number of leucocytes. C M W

- WANG (C W) Solustibosan in Treatment of Kala Azar in Chinese Hamsters.—*Proc. Soc. Experim. Biol. & Med.* 1939 May Vol 41 No 1 pp 152-155

The authors have found that in the treatment of Chinese hamsters, daily subcutaneous injections of solustibosan (120 mgm. of Sb) for

10 to 25 days showed a lower cure rate than neostibosan (168 mgm. of Sb) given in the same way over the same period. Further more the curative effect of solustibosan did not increase with the increase of the frequency of injections. Daily injections of either drug appear to be less effective than bi weekly or tri weekly injections. This result probably depends on the fact demonstrated by BRAHMA CHARI that when the antimony in the tissues reaches a certain level the excretion by the kidneys becomes suddenly increased out of all proportion to the antimony in the tissues. C M W

AVERSA (Tommaso) Primi tentativi di cura della leishmaniosi viscerale infantile col solustibosan (Nota preventiva.) [Treatment of Infantile Kala Azar with Solustibosan.]—*Pediatrics* 1939 June. Vol. 47 No 6 pp 486-489

Very good results have followed the use of solustibosan in the treatment of five cases of infantile kala azar in Messina. The preparation was better tolerated than other organic antimonials.

C M W

MIRZOJAN (N. A.) Traitement de la leishmaniose viscérale par la sourmine [Treatment of Kala Azar by Sourmine]—*Med Parasit & Parasitic Dis* Moscow 1938. Vol. 7 No 4 [In Russian pp 596-605 [15 refs] French summary p 605]

The paper reports that the synthetic organic antimony preparation named sourmine and prepared in the USSR is very efficacious in the treatment of visceral leishmaniasis in Samarkand.

According to the constitutional formula given in the text sourmine is the sodium salt of 3-chloro-4-acetylamino phenylstibonic acid i.e. it is identical with the German drug stibosan which was the first improvement on stibacetin and was discarded in favour of von Heyden 693 which was in turn replaced by neostibosan.

C M W

DAS GUPTA (N. C.) Allergie (?) Symptoms in Cases of Kala-Azar treated with Antimony Salts.—*Jl Indian Med Assoc* 1939 Jan. Vol. 8. No 4 p 237

Two cases are mentioned in which allergic symptoms developed shortly after the intravenous injection of a dose of ureastibamine for the treatment of kala azar. In both cases there was the development over the body of an urticaria like eruption. One patient became unconscious while the other developed uterine haemorrhage. The author says that such cases were common in the early days of ureastibamine but since smaller doses (0.01 to 0.10 gm.) have been given the allergic symptoms have not been seen while the treatment has been quite effective.

C M W

POGGI (Igino) & MONTE (Giuseppe) Esteso focolaio endemico di leishmaniosi cutanea in Provincia di Forlì. [Large Endemic Focus of Oriental Sore in the Province of Forlì.]—*Ann d'Igiene* 1939 June Vol 49 No 6 pp 375-379 With 2 figs & 1 map

The authors have shown that oriental sore is common in the villages of the valley of the Conca in the province of Forlì, in Italy. It appears

in two there were mucosal lesions only. Fouadin administered intra muscularly appears to be the treatment of choice for these conditions. The recent discovery in Brazil and northern Argentine of cases of visceral leishmaniasis leads the author to suspect that cases will be discovered in Yacacuy. He recalls that the first case of kala azar in S. America to be recorded was one seen by MIGONE in 1913 in Asuncion while two cases were noted by MAZZA in 1928 in the Argentine.

C M W

WEINMAN (David). Factors affecting the Morphology of *Leishmania tropica*. The Production of Leishmaniasis Forms in Cultures.—*Parasitology* 1939 July, Vol 31 No 2 pp 185-192. [16 refs.]

The paper describes experiments which have shown that under certain conditions of culture the flagellate forms of leishmania will be transformed into the tissue-invading leishmania forms. Though the guineapig is refractory to inoculation with leishmania and though the parasite will not develop in guineapig tissue cultures, it will multiply in pieces of guineapig tissue (spleen or lung) which are placed on the surface of the NNN blood agar or Zinsser's serum-Tyrode agar. The pieces of tissue about 2.5 mm in diameter are removed from the animal aseptically, washed in Tyrode's solution and then bathed in rich culture from tubes of NNN medium for 15 to 30 minutes. The pieces of tissue are then placed on the agar slopes and incubated at 33° to 37°C. The cells of the tissue appear to survive for eleven days or longer during which living leptomonads live and multiply in the drop of the liquid which collects round each piece of tissue while in the tissue itself typical leishmania forms appear and multiply. The best results were obtained with guineapig lung, though the spleen of this animal and even that of the frog behaved similarly. The serum Tyrode-agar was prepared as follows. To 150 cc. of 3 per cent. agar at 50°C is added a mixture (warmed to 30°C.) consisting of 150 cc. of sterile double strength Tyrode solution, 100 cc. of horse serum and 8 cc. of 0.04 per cent. aqueous solution of phenol red. After mixing the medium is tubed and slanted. After sterility has been proved by incubation the cotton plugs are replaced by rubber caps and the tubes stored at 8°-10°C. Tubes three months old have given satisfactory results.

C M IV

ENQUIRIES

To the Director

Bureau of Hygiene & Tropical Diseases.

Sir

In regard to your correspondent's request [this *Bulletin*, 1939 Vol. 36, p. 789] for any reference to viability of hookworm eggs in sewage after tank treatment, it is but just to Ch. Wardell Smith to point out that evidence for such destruction in household septic tanks goes back to his pioneer work published in 1911. In his first Annual Report as Scientific Secretary of the Rockefeller Sanitary Commission for the Eradication of Hookworm Disease he reported that when faecal material was subjected to decomposition in water for 70 days nearly all, and when so subjected for 117 days all, hookworm eggs were dead, and in these conditions, at least 80 per cent. of *Ascaris* eggs were dead in four months.

These observations were made to test the value of the L.R.S. (Lumaden Roberts Stilcs) privy designed for one country family and described in U.S. *Public Health Reports* 1910 Nov 11 another description of it followed in the *Farmer's Bulletin* 463 of the U.S. Department of Agriculture 1911 while that of a modification in concrete appeared in *Public Health Bulletin* No 68 issued in 1917 by the Treasury Department U.S. Public Health Service On the L.R.S. privy was based the Aqua privy a factory made concrete cylinder with drowned unscreened outlet [LANE 1917 *Indian Jl Med Res* Vol. 5 p 350 and Hookworm Infection 1932, p 253] In all these privies the practical sanitary point in view is the prevention by the effluent of the conveyance to the soil of any but dead and thereby lightened eggs no longer lying in the sediment for currents in the tank must not disturb the sediment for that purpose the design of the concrete L.R.S. privy seems to be the best for the family of a country homestead

Yours etc.

October 2 1939

Clayton LANE

REVIEWS AND NOTICES

RICHARDS (Audrey I) [M.A.(Cantab) Ph.D (London) etc.] *Land, Labour and Diet in Northern Rhodesia An Economic Study of the Bemba Tribe*—pp xiv+415 With 16 plates 5 figs. 2 maps & 1 chart. Published for the International Institute of African Languages & Cultures. 1939 London New York Toronto Humphrey Milford, Oxford University Press [30s.]

This book deals with every aspect of the diet of the Bemba, from the preparation of the gardens and sowing of the seed or the gathering of the leaves of wild plants to the sharing-out of the cooked meal to the members of the family circle The apportioning of land to the head of the family and the effect on the agricultural output in the villages of prolonged absence of the males at the mines or European plantations are also discussed.

Charts and Tables are given showing how the men and women occupy their time when at home the kinship composition of a village and the individual intake of flour from day to day in family groups.

The Bemba better known as the Aweremba to those familiar with North East Rhodesia in its early days were a warrior tribe with a highly developed political system The paramount chief exercised a rigid control over his subjects and was entitled to exact free labour from them for his own or for tribal business In the course of the last half-century or less the tribe has had to adapt itself to a peaceful agricultural existence. Latterly has come the attraction of work at the mines at wages which bring many European made goods within the workers reach.

The mode of life of the Bemba has therefore undergone more radical changes than has that of most African tribes and they hardly seem to have completely adapted themselves to the changed conditions. As agriculturists for instance they are distinctly backward. For this reason it is questionable whether a wise choice was made in the Bemba when seeking a tribe to be the subject of a dietetic study

In a Foreword to the volume Dr Richards modestly states as her aim, the giving of a broad idea of the extent and variety of nutritional

JACK (Rupert W) [Chief Entomologist]. *Studies in the Physiology and Behaviour of Glossina morsitans* Westw.—*Southern Rhodesia Memoirs of the Department of Agriculture* No 1 1939 May pp 203—vii With 27 figs & 3 plates. [37 refs.] Salisbury Govt Stationery Office

The first serious account of laboratory work on the physiology of the tsetse fly was published by Burton and Lewis in 1934 [this *Bulletin* 1935 Vol 32, p 389]. Since then a good deal of similar work has been done and considerable progress has been made but the paper under consideration is the first detailed account of experiments in the laboratory using *Glossina morsitans*. It describes a large number of experiments made mainly in Salisbury by Mr R. W. Jack and his technical assistants.

The results are given in two main sections, the first dealing primarily with physiology and the second with behaviour. The reactions of the adult and pupa were determined under a variety of conditions of temperature and humidity. The results are generally similar to those obtained using other species of tsetse. The insect is seen to be adversely affected by extremes of heat, cold and dryness. On certain processes, e.g. fat metabolism the author tries to assess the effects of the unnatural conditions inseparable from captivity. The experiments on the behaviour of the flies and their reactions to light and other stimuli are of interest, though it is not certain whether they always indicate the reactions of the wild fly in the field.

The present reviewer considers that all these laboratory experiments reveal something of the physiology of the insect concerned, provided that caution is exercised in the interpretation of the results. Only by laboratory work can we hope to understand fully the physiology of the tsetse and until the physiology is really understood, satisfactory and permanent control is unlikely. Unfortunately the kind of information obtained in the laboratory is not always of direct practical value and it is even possible that with misinterpretation it may in practice do more harm than good if the results are applied indiscriminately in the field. Laboratory workers are aware of this and are afraid that their methods may sometimes come into disrepute if the results are put into practice too soon. The information contained in the paper under consideration will serve as a basis for further exact knowledge of *Glossina morsitans* even if the interpretations the author gives may sometimes have to be modified.

Most tsetse workers seem to have some difficulty in fixing on suitable units for expressing their data. In this paper the normal metric units (including the Centigrade thermometer) are used as a rule but occasionally the author breaks out into millibars and Fahrenheit and on one occasion he gives the saturation deficiency of the air in grams per cubic meter—a unit the reviewer has never found before even in the tsetse literature. Strict uniformity in these matters is surely desirable.

Kenneth Mellanby

INDEX OF SUBJECTS

(The entries in heavy type refer to Sections in which abstracts on the subject indicated are grouped together. Page numbers within brackets indicate papers cited by title only.)

- Abscess caused by *Aereria* 321 722
Acantbochromium perle : infection treatment by methylene blue, 641
 Acclimatization of white races in tropics, 945, (946)
 Achromia
 in America Central, 103
 West Indies 103
 Acres poisoning experimental, 412
 Adenitis in leptospirosis, 771
 Addison's disease malarial, 814
Adies eryth and see **YELLOW FEVER**
 development of *P. banroffii* in, 130
 distribution
 in Gold Coast, 28
 Kenya, 28
 Nigeria, 28
 Sudan, 28
granulatus
 behaviour of yellow fever virus in, 638
 breeding places of, 638
 transmitting *P. gallinaceus* 638
 solitarily transmitting *P. catenellatus*, 357
interitus
 behaviour of yellow fever virus in, 639
 susceptibility to yellow fever virus experiments, 638
 Africa, conquest of, for white and coloured races, (949)
 Agrostolocytes due to quinine 497
 Aircraft
 staphylococci found on, 640
 disinfection of
 by Deakoto when in flight 31 32
 Larimath spray ejector 3rd 643
 Phantomyst nebulizer 31 3rd 403 643
 malaria dissemination and 1006
 and transmission of disease 640 643, 648, 647 973 1006
 Air ports plague and 973
 Alcoholism pellagra and 543
 Amara, 418
 diagnosis differential from smallpox, 418
Ambsi's barometer intermediary of *Moscheromyia yakopae* 43
 Ammonium sulphat as combined fertilizer and mosquito larvicide 1009
 Amoebae
 action of quinine on, 304
 muculated into cat by laparotomy 305
AMORBIASIS, 281-303
 in Cuba, 293
 Italian East Africa, 283
 Japan
 Isle of Japan 36
 Taiboku school-children, 584
 Shanghai hospital patients, 594
 U.S.A. 246
 Los Angeles, 292
 Amoebiasis see also *Entamoeba histolytica*
 aetiology 290
 carrier problem, 289
 colitis, cutaneous, histamine reaction in, 28
 treatment by focarsons, 303
 diagnosis
 complement fixation test, 294
 differential, erythrocyte sedimentation rate, 293
 sigmoidoscopy, value of, 293
 in dogs, experimental, 290
 epidemiology (254)
 experimental, 290
 hepatitis, 300
 in U.S.A. 290
 blood in, 300
 liver abscess, 296, 298
 in Caylon, 298
 Indo-China, 296
 U.S.A., 296
 complications, 298
 lung cyst associated with, 295
 treatment, 296 298, 299
 mental syndromes (296)
 from nasopharyngeal polyp, 293
 in naval crew 283
 non oral syndromes, (296)
 parasites and, 296
 pathogenesis, 288 292
 prophylaxis, (284)
 role of bacterial flora, 290 291
 toxic colitis favouring, 292
 treatment, 304
 emetine, 293
 carbazone, 302
 toxic symptoms following 302
 chemotherapy 303
 emetine, 296, 301
 yates, 298 295
ANAMIA
 among Assam tea estate labourers, 8
 of Uganda, 836
 in alkylotomiasis, 838
 aplastic
 fatal case, 938
 resemblance to myeloid, 938
 Bartonella
 immunity in, 436
 infection of rats, 486
 diagnosis, 938
 in helminthiasis, (36)
 hyperchromic
 rare forms, 938
 treatment by ferrous sulphate 938
 hypochromic
 idiopathic, 474
 secondary to multiple parasitism, (36)
 iron-deficiency 324
 of kala azar 1029

Anaemia—cont

- macrocytic
 - aetiology 835
 - nutritional, in Macedonia 422
 - red cell fragility in 838
- and malaria, 130 839 840
 - treatment by atehrin, 839
- nutritional macrocytic in Macedonia 422
- pernicious, and sprue (82)
- in pregnant coolie women in Indian tea gardens 418
- sickle-cell
 - differential diagnosis, 837
 - erythrocytes in, 838
- treatment by liver and vitamins B and C 938

Ancylostoma caninum

- in Surinam dogs, 156
- carbohydrate metabolism 325
- larvae experiments, 325
- duodenal larvae capture by soil fungi 833

Ankylostomiasis see also Necator infection

- in Argentine 325
- Assam Valley coolies 508
- Batavia 145
- Ceylon, 828
- China
 - Hunan, Shaoyang, 829
 - North, 318
 - Peiping, 144
 - Shanghai hospital patients 594
- Egypt, 38
- France 322
 - in miners 833
- Japan
 - Ishigaki Island 36
 - Taiboku school-children 594
- Nigeria, Lagos, 691
- Resistencia (Chaco) 323
- Ruanda Ruhengeri, 592
- Somaliland, 828
- Trinidad, (828)
- U.S.A. Florida 828
- Venezuela, 583

- anaemia in 838
- blackwater fever and, 839
- control in Egypt, 36
- diagnosis differential, erythrocyte sedimentation rate, 833
- in dogs, vaccination, 833
- intestinal, 322
- lesions, intestinal histopathology of, (834)
- prophylaxis 833

Subject Index

Typhus Group of Fevers—cont

- epidemic typhus
 - in Algeria, 938
 - Brazil Minas Geraes 478 998 999
 - Casablanca, in naval personnel, 989
 - Ethiopia 939 1001
 - Morocco, 1000
 - in naval personnel 989
 - Shanghai, 464
 - South Africa, 463, 996
 - Venezuela, 470
- chloride metabolism disturbances (996)
 - diagnosis, 999
 - prophylaxis 988
 - in Morocco 988
 - statistics, French North Africa 988
 - vaccination, 1000
 - Blanc method, 1001
 - dried murine typhus virus 471
 - Weigl's vaccine 1001
- virus
 - differentiation 473
 - of Minas Geraes variety 998 999
 - exanthematic *see* epidemic typhus
 - experimental
 - acceleration of sedimentation of red blood cells in guinea pig 984
 - five-day fever 996
 - mite fever (pseudotyphus) reinfection, 479
 - murine typhus
 - in Greece 470
 - South Africa 463
 - chloride metabolism disturbances (996)
 - diagnosis
 - differential from boutonneuse fever 470
 - feeding of rats on food contaminated with patients urine 994
 - experiments with Tongkinese natives, 993
 - immunity cutaneous, of rabbit, 982
 - periculis in, 992
 - transmission, 464
 - experimental by respiratory route 463
 - virus
 - cultivation, experimental 993
 - differentiation 473
 - experiments, 467
 - on rats, 994
 - identification, 992
 - isolation, 992
 - in Peking house rats, (994)
 - on Zinsser agar tissue media, 992
 - modification of pathogenic activity during passage in white mice 993
 - persistence of, in tissues of experimental animals 466
 - virulence of for white mice 994
 - prophylaxis 471
 - pseudotyphus (mite fever) reinfection, 479
 - Rickettsia
 - growth on agar tissue cultures 992, 1002
 - and *Proctos* X19 antibodies dissociation of in experimental infections, 472
 - reaction to lugol of cells containing, 984
 - staining
 - iodine, 984
 - rapid, with thionine 468

Typhus Group of Fevers—cont

- Rocky Mountain fever
 - in Canada 967
 - U.S.A. 991
- Massachusetts 474
- atypical 993
- survey in
 - Canada Western 474
 - Iowa, 475
- virus
 - cultivation agar slant tissue 998
 - use of yolk sac of developing chick embryo 984
 - differentiation 473
 - persistence of in tissues of experimental animals 466
 - transmission experiments with triatomid bugs, 998
 - Weil Felix reaction in 477
- São Paulo typhus
 - in Minas Geraes, 478
 - dog as likely reservoir 477 478
 - pathology 478
 - vectors, 477
 - serology (469)
 - serum and spinal fluid protein content and polypeptides, variation of, (469)
- Summary of Recent Abstracts 797-803
- tick bite fever
 - in Montana, 986
 - South Africa, 463 996 997
- complications, 997
- of Montana and Q fever similarity between, 986
- transmission
 - Amblyomma hebraeum* from veldt rodents, in South Africa, 996
 - H. leachi* from dogs in South Africa, 996
 - ticks, filter passing infectious agent isolated from 479
- treatment, 471
- sallylate of mercury ineffectiveness of 989
- vitamin, 989
- tropical typhus, (469) 996
- without rash, 1000
- tetracycline disease
 - in Hanoi, 999
 - Pescadore Islands 1000
- Typhus Bacteriology and Immunology Studies on (book review)
- like fevers
 - in Federated Malay States, 463
 - spontaneous caused by new species Rickettsia of louse, 985
- vaccination, 471
- serological studies of vaccinated person 468
- Zinsser-Castaneda vaccine, 1002
- virus
 - cultivation, use of yolk sac of developing chick embryo 984
 - differentiation 473
 - isolated in Shanghai, 983
 - without rash 989 995

Ulcers

- chronic, treatment by
 - formalin, 343
 - sulphasulamide 349
- tropical
 - in Belgian Congo 406
 - French Colonies 1833 406
- etiology 507
- diet and, 507
- treatment 505
- cod-liver oil dressing, 503
- prophylaxis 349

Undulant fever

- in Malta, 94
- diagnosis, differential erythrocyte sedimentation rate 833

treatment

- Brucella abortus* 943
- sulphasulamide 187 942, (943)
- (Astreptin) 803

[Supplement to the *Tropical Diseases Bulletin* 1939 November]

YAWS (*Framboesia Tropica*) IN THE BRITISH WEST INDIES

THE CONTENTS OF ANNUAL REPORTS IN 1937

By P. GRANVILLE EDGE.

*Lecturer in the Department of Epidemiology and Vital Statistics London
School of Hygiene and Tropical Medicine (University of London)*

At a time when the eighteenth century was hurrying to its close and Europe rang with the noises of the great social upheavals which were to introduce a new era in the Political History of the Continent a Spanish epidemiologist was stimulated to embark upon a work of some scientific importance. In this work he promised to discuss the actuating causes of various diseases according to the opinions of medical men who had studied them at different periods of time to present the means which knowledge derived from experience had proved the most efficacious for their prevention or cure and to comment upon the general sanitary measures taken by Governmental and other authorities from time to time in the interests of Public Health.

This admirable intention ultimately gave birth to a treatise entitled *Epidemiologia Española* from the pen of Don Joachim de Villalba and published at Madrid in 1803.

The exuberant title⁽¹⁾ advertising the extensive scope of this work served to excite the scientific appetites of medical investigators of other countries and led them to sample the dish⁽²⁾ prepared by a well-qualified and capable *chef de cuisine épidémiologique*⁽³⁾ who complained that valuable epidemiological studies and vast stores of medical knowledge resulting from the efforts of Spanish investigators throughout the ages were either unknown or purposely neglected by their foreign colleagues⁽⁴⁾.

This reference to the work of VILLALBA has been made because despite the passage of over a century of time the complaint he voiced has a familiar sound. Medical investigators of the present day may be heard resentfully protesting that the results of their work fail to receive the attention their importance merits. Among scientific explorers in this category may be included many Colonial Medical Officers who sometimes feel that their difficult work in remote places receives but scant consideration. They have not been unknown to

(1) *Epidemiologia Española ó Historia Cronológica de las Pestes Contagiosas, Epidemias y Epizootias que han acaído en España desde la venida de los Cartagineses hasta el año 1801. Con noticia de algunas otras enfermedades de esta especie que han sufrido los Españoles en otros Reynos y de los autores nacionales que han escrito sobre esta materia así en la Península como fuera de ella* Joachim de Villalba. 2. Tom. Madrid 1803.

(2) Hecker and others have quoted freely from this work.

(3) Villalba loc. cit. Title-page.

(4) He speaks rather bitterly of the reproaches falling from the lips of the ungrateful foreigner—*¡sufierimos el labio mordido del ingrato extranjero!*—adding that foreign writers failed to consult the medical works of the nation, etc.—*no solo no han consultado las obras medicas de nuestra nacion*—loc. cit. p. x. Intro.

declare that Annual Medical Reports are rarely worth the expense of labour and money devoted to their compilation, since completed documents may serve only to add to the accumulations of printed waste which characterize the dusty shelves of some Government Departments.

These complaints are sufficiently loud, but—so far as Colonial Medical Reports are concerned—are they always just? Certainly it cannot be denied that some Reports receive no more attention than is given them by those, who by virtue of official necessity are compelled to read them. But in such cases can it always be claimed that the fault lies entirely with a vaguely conceived reading Public or is it possible that the indifference complained of may sometimes be due to shortcomings inherent in the Reports themselves? (1)

Regular readers of these *Supplements* will recollect that in earlier issues it was stated that records of sickness were of first-rate epidemiological importance and scientific value (2) and that an attempt would be made each year to select *some disease of outstanding importance in the Colonies and from the Colonial Medical Reports prepare a summary of the varied experiences in different territories etc.* (3) Proceeding to implement the latter intention we hope the discussion which follows will not have proved unsuccessful in persuading the reader to agree that the apparent irrelevancies which have characterized the introductory paragraphs of this essay have some significance.

For purposes of the present summary first this and then that disease title was selected considered and then—for reasons calling for no discussion on the present occasion—discarded. Finally *yaws* was decided upon but owing to limits of time and the exigencies of printed space it was found necessary to confine discussion of the distribution and incidence of the disease to recorded experiences within the boundaries of a single geographical entity. These considerations ultimately led to the choice of the cluster of islands lying between North and South America (including British Honduras in Central America and British Guiana the only British Colony on the mainland of South America) the whole grouped under the embracing title of *The British West Indies*.

An abundant literature evidences the presence of *yaws* in these territories from the time when African slaves were first introduced at the beginning of the 16th century (4). Thenceforward the disease

Report on Yaws—H. A. Nichols H. V. Stationery Office 1894 pp. 11–13–14.

An admirable bibliography is contained in the monograph *F. Ambrosia Tropica* by E. H. Hermann, Leyden 1931 pp. 153–163.

spread rapidly became endemic in many islands and was the cause of such extensive disability as to give rise to considerable anxiety on the part of the old planters to whom the physical welfare of their slaves was a matter of constant concern (1). Steps were taken to deal with the problem with the result that by stringent segregation and the regular treatment of cases in *yaws houses* (2) conditions underwent such striking improvement that the disease is said to have entirely disappeared from some islands previously heavily infected (3).

However after the emancipation of the slaves in 1834 this system of control came to an end for the negro found himself free to come and go at will. Many of them proceeded to settle in remote or mountainous tracts of the various islands beyond the reach of civilizing influences and the medical treatment of active cases. Infected persons thus acted as foci for the rapid dissemination of the disease which became endemic in some areas and reappeared in several of the islands from which it had formerly been stamped out (4).

From that time forward and until towards the last quarter of the 19th century little seems to have been known of the incidence or distribution of the disease in the West Indian Islands for lacking Governmental care and supervision the negroes appear to have treated themselves or to have sought the doubtful remedies of the native bush-doctor or *obeahman*. During this period *yaws* seems to have disappeared from official records and its very existence was perhaps doubted (5) yet when local Governments were started to realize their responsibilities and began to devote attention to the well being of the people it at once became evident that the evil persisted to a menacing extent was increasing had invaded areas in which previously it was unknown and altogether constituted a serious health problem.

Though steps were thereupon taken to deal with this loathsome contagion with a view to its control and ultimate eradication a number of factors combined to hamper progress. Familiarity with the disease over a long period of time had contrived to make the people lose any fears they may have had of the infection. The belief was well established that infection was inevitable and that the younger the patient the less virulent the course of the disease with the result that contact of healthy with infected persons was actually encouraged. Facilities for proper medical treatment when provided were largely ignored for there had developed a prejudice against treatment by medical officers arising from the belief that only the native bush-doctor and his like understood the nature and cure of the disease. In these circumstances it is scarcely surprising that cases continued

Reports on Yaws—T. I. Tulloch. (Three issued between 1883 and 1890.)

(2) *Yaws Houses* are described by both Tulloch and Nicholls. There is a "*Yaws Bay*" on Carriacou (an island of the Grenadines attached to Grenada) which may indicate the site of a former *yaws house*.

(3) These were said to include Barbados, Antigua, St. Kitts, Carriacou etc.

(4) Cf. Nicholls, *loc. cit.* pp. 14-15.

A Descriptive Account of Framboesia or Yaws—D. Mason. Edinburgh. *Med. & Surg. Jour.* XXXV. 1831.

(5) Very little if anything was heard of *yaws*, its name even forgotten in some places.—Nicholls, *loc. cit.* p. 14.

to be concealed from professional observation, thus providing scattered reservoirs of infection for the continued spread of the disease.

However efforts on the part of the medical authorities were continued with praiseworthy zeal. Superstitions and beliefs were difficult to overcome but with the gradualness of time more and more people were brought to realize that medical officers did understand the disease and its treatment and could provide relief and cure for sufferers who regularly followed their advice. By the beginning of the 20th century yaws was practically eradicated from many of the islands and in others the number of new cases discovered each year steadily decreased. It seemed reasonable to predict that in a near future complete freedom from the scourge would follow the continuance of these efforts.

Unhappily unforeseen circumstances and conditions of one kind or another arose from time to time demanding the reduction or temporary abandonment of regular treatment services and also it will be remembered that no really efficient means of treating the disease existed prior to the introduction of the Salvarsan compounds and later Bismuth. The malady was thus provided with opportunities for increased spread in some areas, re-infection of others from which it had been eradicated, and introduction of the infection to districts where previously it had not been believed to exist. So for the first thirty years or so of the 20th century the authorities continued an unequal fight hampered by the crippling disadvantages of insufficient funds and shortage of staffs, and experiencing as great difficulty in persuading infected persons to submit to rational and regular treatment, as did their colleagues in pre 20th century days.

And what of the situation in 1937?

With a view to discovering an answer to this question, the Annual Medical Reports for the years 1934-1937 were examined. These Reports deal with health experiences in 17 separate administrative units comprising British Possessions in the West Indies, and having an aggregate population of approximately 2,375,000 persons.

The results of the investigation incline the present writer to observe that accounts as presented in Annual Reports do not adequately represent the scope of work carried out in connexion with yaws in the territories under review. Though it is known that the disease is still the cause of considerable disability in the Islands, with the single exception of Jamaica⁽¹⁾ references to this highly contagious ailment were somewhat scanty. On the other hand it is to be remembered that Annual Reports cannot possibly present all the knowledge of a specific disease assembled by Medical Officers in the course of their year's work. It is not suggested that yaws any more than any other disease, should receive special attention, but it is probably true that the Reports under review do not do justice to the general interest in the specific disease with which this summary is concerned.

(1) In Jamaica through the co-operation of the Rockefeller Foundation a special Yaws Commission was organized in 1931. The yaws problem was dealt with on systematic lines and an admirable series of detailed reports of this work is available (see also pp 7 & 11 *infra*). The Medical Department has now assumed full responsibility for the continuance of the campaign which is effecting steady reduction in the numbers of active and infectious cases.

Facts the only starting point of all epidemiological knowledge are incomplete variously stated in different parts of the same Report or where they are entirely lacking their lack is replaced by the submission of unconvincing personal opinions.

For example as the disease is not mentioned in 6 out of 17 Reports examined, we assume *yaws* does not exist in these areas ⁽¹⁾ In the remaining 11 affected administrative territories 47,862 cases were recorded during 1937 and of this total over 30 000 were recorded in Jamaica the only Colony where an intensive and systematically organized campaign against the disease was being waged. In one Colony where it was observed that *incidence did not vary very much from previous years* almost in the same breath follows the statement that *again it must be recorded that there was an increase in the incidence* ⁽²⁾ In another Colony it was said *The disease is slowly and steadily disappearing* though how slowly or how steadily we are left to conjecture for no record of cases is supplied. In another Colony we are told that 11.6 per cent. of all the diseases in the Districts were cases of *yaws* and then that 1 108 cases were notified only to find in another section of the same Report that 1 611 cases of the disease were dealt with in one District alone Within the boundaries of the same Colony one District Medical Officer will report incidence to be 'decreasing' another that it is 'increasing' ⁽³⁾ while in some areas the inclination lies towards announcing the numbers of injections given during the year in place of the numbers of patients treated

These brief references may suffice to indicate that though for two and a half centuries or so *yaws* has persisted as a significant feature of health experience in the islands comprising the British West Indies it was not possible to discover from Annual Medical Reports in 1937 any dependable numerical expression of collective experience. Precise accuracy is not attainable but there are degrees of inaccuracy and it is suggested that reliable methods of record keeping would provide reasonably complete data for comparative purposes.

Such *aetiological aspects* of the disease as the effects of environmental conditions sex, age or other influences which combine to produce and maintain the infection among the people of certain islands cannot reasonably be discussed at length in Annual Reports unless new facts of outstanding importance have been discovered in any particular year. Whenever possible however it would be of value if records of age and sex incidence ⁽⁴⁾ were provided for diseases responsible for excessive disability. Diseases are not static—the predisposing or contributory factors in various combinations in different areas may profoundly

(1) In the main these areas enjoy relatively dry climatic conditions surface features are characterized by an absence of densely forested mountainous tracts. Cf. *Attitude of the Medical Profession towards Yaws*—C. W. Branch, *Amer Trop Med & Parasit.* Vol. 1 No. 3 Nov 1907 p 405

(2) Actually a 53 per cent. increase over the experience of the preceding year was recorded in 1937

(3) These varied experiences are well known to occur. It would be of interest to be told what probable causes underlie these manifestations.

(4) In one or two Reports Hospital *in-patient* cases are classified by sex alone the numbers of *yaws* cases treated as in-patients are insignificant. Informative Reports were issued by members of the Staff of the *Yaws* Commission of the Rockefeller Foundation among others see—

Age distribution and infection rate in Jamaica—G. M. Saunders and H. Muench. *Amer Jour Hyg.* Vol. 28 1937 pp 423-6.

alter clinical manifestations between place and place and lead workers to record widely divergent conclusions (2) The disease flourishes under conditions of poverty and squalor and is rare among a cleanly people Though not discussed with specific reference to yaws the piecing together of scattered items of information relating to living conditions in areas where cases are recorded, suggests that the whole environment favours the survival and propagation of the causal agents of the disease (3) Reported cases often occur in rural areas where poverty and ignorance are characteristic features, where sanitary conditions are unsatisfactory where there is a lack of control of housing conditions, and where nutritional diseases are common (4) It may be noted that similar conditions exist in greater or lesser degree in some of the Islands from which no cases of yaws are reported

Attempts are rarely made in the Reports under review to discuss the proportions of patients examined showing primary secondary and tertiary stages of the disease including the late tertiary stages characterized by bone lesions and chronic ulcerations. These data are important for comparative purposes it is known for example (not necessarily in the West Indies) that a diagnosis of tertiary yaws is often made on unconfirmed clinical evidence Hospital and dispensary returns suggest that skin and bone diseases, abscesses and ulcers are likely to be more common where yaws is prevalent—though these phenomena may merely reflect methods of hospital book-keeping If each time a patient is treated for the same cause he happens to be recorded as a new case What connexions exist between these manifestations and yaws prevalence are left an open question one such reference only was discoverable in the observation of a District Medical Officer who says

From 5-10 years is the age during which the disease is most likely to occur and From infancy to old age, males are more frequently affected than females — Nicholls, loc cit pp 281-282

- (2) In recent paper for which the Author was awarded the North Borneo Forces Medal for 1938, the relationship of yaws to environment is discussed the following observation also occurs —

Reference is made in Manson's *Tropical Diseases* (1933) to the presence of the spirochaete in the floors and walls of native huts This finding supports the writer's observations for in the West series the primary sore was in most cases situated on the genital regions due, it is thought, to the habits of the unclothed children sitting together on the ground *Yaws and its Treatment* — T Simpson *W African Med Jour* Vol X, No 1 October 1933 pp 17

- (3) Appendix VI of the Supplement to the *British Medical Journal*, June 24th, 1936 records the evidence submitted by the British Medical Association to the Royal Commission on the West Indies discussing the Medical Services in the West Indies In Table II of this Appendix under the title of Diseases possibly indicating Bad Social Conditions are tabulated the available facts called from Annual Medical Reports for 1936 Yaws is one of the diseases recorded and is described as "another prevalent cause of ill-health"

I have no doubt that a fair percentage of the ulcers are *pian* in origin now masked by superadded infections (1)

Open ulcers are especially attractive to flies and as the species *Hippelates pallipes* is commonly met with in the Islands while these insects may play no major rôle in the transmission of infections (2) it is possible they may be to some extent responsible for the propagation of the disease. During 1933 and 1934 the special *Yaws Commission* of the Rockefeller Foundation working in Jamaica undertook special entomological studies concerned with the anatomy physiology and life habits of *Hippelates* flies with results which tended to show that *H. pallipes* might be the natural vector of *yaws* (3). Admittedly these views are at present conjectural but research work is usually prompted by guessing at the causes of phenomena and competent workers are of the opinion that this aspect of the *yaws* problem is worthy of further study (4).

(4) For example A house fly a species of *Musca* is very common. This fly as a result of its regurgitant habits may be a factor in carrying the infection to non-specific sores and wounds of otherwise healthy individuals. It is hoped at a later date to be able to study this phenomena in some detail.—Simpson. *loc cit* p. 17

Under the title of *Treatment* Reporting Officers confine their remarks to such statements as "bismuth is the drug of choice, that "injections of arsenic or bismuth were given" or that "treatment was continued on the same lines". As regards the latter phrase the same statement was found to have been repeated previously in five successive Annual Reports relating to one Colony. These matters received the studied attention of the *Yaws Commission* of the Rockefeller Foundation during the course of their investigations in Jamaica, and several valuable reports were issued describing their findings in great detail.⁽¹⁾

But in this connexion it is well to bear in mind that the limited space available in Annual Reports makes it impossible to discuss within their pages such matters as the successive dosages of drugs used during the course of treatment, their graduation with respect to the age of patients, the preparation of bismuth or arsenic used, the average numbers of injections necessary to effect cure, the intervals of time between successive injections, disagreeable after-effects, if any, or intolerance to specific drugs and so on. Information on these points is usually reserved for publication in special reports, scientific journals, etc. though so far as *yaws* is concerned, such papers are by no means abundant. It would be a useful feature of Annual Reports if brief mention could be made of published papers, or of any work in progress designed to extend the boundaries of existing knowledge. There is little doubt that given the opportunity Medical Officers with extended experience of *yaws* in the West Indies would have much of interest and scientific value to say of the rapidity with which lesions clear up as the result of specific therapeutic action and modes of administration of various drugs, of the proportion of relapses occurring among cases previously treated, of *yaws* patients suffering from some concurrent disease demanding two forms of treatment and thus complicating the difficulties of assessing the results of treatment for *yaws* alone. The importance of these matters is recognized by all Colonial Medical Authorities and from time to time results are discussed in the pages of this or that scientific journal. But would not a useful purpose be served if it was found possible to make brief mention in Annual Reports of the more important items of information recorded by Medical Officers whose valuable work does not always receive the attention it deserves?

If results of treatment are systematically checked by serological examinations such results should be recorded in Annual Reports. Facilities for such work are not at present available in many of the Islands. Lacking adequate laboratory equipment and trained technicians it becomes impossible to determine how many injections of a specific drug are necessary to produce unmistakable Wassermann or Kahn negative reactions, and what proportion of cases if any show positive reactions after a full course of treatment. Here again reference must be made to the valuable comparative studies on the

(1) Cf. *Yaws in Jamaica*—A plan of control based on Treatment.—H. M. Johnston and G. M. Saunders. *Amer Jour Hyg* Vol 91 pp 522-559 May 1935

Control of Yaws by alternate treatment method—G. M. Saunders. *Amer Jour Trop Med* Vol 17 pp 335-347 May 1937

relationship of *yaws* and *syphilis* carried out by the *Yaws Commission* of the Rockefeller Foundation in Jamaica results being discussed in the Report of the *Yaws Commission* for 1934 and in various scientific journals.⁽¹⁾

As regards *research work* the responsible Medical Authorities in these Islands are eager and ready to undertake and continue with schemes of research which would serve to extend the enquiries so admirably planned and carried out in Jamaica by the *Yaws Commission* of the Rockefeller Foundation but unfortunately research work is costly and financial considerations have up to the present prohibited resumption of these investigations on a large scale. So far as the British West Indies are concerned research work is usually regarded as being confined to the valuable investigations of various kinds which have so long been carried out in the established laboratories of Jamaica and Trinidad. But on the other hand though lacking laboratory equipment and trained *personnel* for the purpose Medical Officers in many of the smaller Islands have often and voluntarily undertaken and successfully carried out original enquiries concerned with public health problems peculiar to their respective areas.

Unfortunately what work of this kind is, or has been done or what special knowledge has been accumulated during the course of independent enquiries is not always nor adequately reported either in Annual Reports or in Medical Journals. Furthermore many Medical Officers must assemble during the course of extended field experience information of value which however they may modestly regard as too insignificant to merit separate publication. The bare mention of some of these items of knowledge in Annual Reports would be of value to other workers.

Admittedly a great deal of knowledge has been accumulated concerning *yaws* but it cannot be denied that much yet remains to be known before it can be claimed that certainty has replaced conjecture in so far as certain features of the disease are concerned. It is not within the scope of this paper to suggest lines of research but there can be no doubt that *field observations constitute an essential part of such work* and these are constantly being made. So far as Annual Reports are concerned it is believed they provide a readily accessible medium for the recording of such observations which otherwise may pass unnoted. For example it is by no means impossible that minor but important points in the *field* application of recognized methods of diagnosis, treatment etc. may be found by extended practical experience to need modification. Such modifications suggested by field workers might well be mentioned in Annual Reports.

Reports relating to different Colonies the textual comments of some contributors are little more than the repetition of the same verbal descriptions from year to year. The annual submission of snippets of comment concerning a wide range of individual diseases or attenuated references to important medical activities are practices which scarcely possess any scientific value. Out of a wealth of experience little real information is released, and as matters stand at present the success of measures adopted in one Colony may be for want of knowledge of the relevant information may not be made available either in scientific journals or in Annual Reports.

The reader may be reminded that in the introductory pages of this essay reference was made to complaints that Annual Reports were often received with indifference(?) and it was hoped that discussion might reveal some of the causes contributing to the apparent unpopularity which clings to this branch of official literature.

Certainly the aim of the *Model Medical and Sanitary Report* was to provide for the preparation of readable Reports of an informative nature and not to create static conditions so far as these Reports are concerned. But some Reporting Officers appear to have defeated this aim by the development of dreary routine methods of work, followed from year to year rather reminiscent of Macaulay's description of Mohère's doctors(?) who thought it more honourable to fail according to routine than to succeed by innovation. (?)

- (1) Cf. p. 4 supra
(2) *Critical and Historical Essay* by Lord Macaulay—London 1877 War of the Spanish Succession p. 259

(3) In *Le Malade Imaginaire* M. Diafoirus, physician is pressing the claims of his son Thomas Diafoirus (also a physician) for the hand of Angélique the daughter of Argan (*Le Malade Imaginaire*) and quotes in his son's favour —
ce que me plaît en lui, et en quoi il suit mon exemple, c'est qu'il attache vigilement aux opinions de nos ancêtres, et que jamais il n'a voulu comprendre ni écouter les raisons et les expériences des prétendues découvertes de notre siècle — Cf. *Le Malade Imaginaire* Act 2. Sc. V. p. 355

and again—
et pourvu l'on suive le courant des règles de l'art, on ne se met point en peine de tout ce qui peut arriver. Loc. cit. p. 358

The Third Interlude to the play describes the burlesque ceremony representing the admission of a candidate to the degree of Doctor of Medicine. This is composed in a mixture of dog-Latin and French and is scarcely translatable in any modern fashion it tells how the candidate is required to swear to follow all the ancient practices and remedies of the Faculty — Cf. *Le Malade Imaginaire* Tome neuvième Œuvres de Molière Libraire Hachette. Paris 1886

In much the same sense Buckle observes —

By encouraging the notion that all the truths most important to know are already known they repress those aspirations, and dull that generous confidence in the future without which nothing really great can be achieved. A people who regard the past with too watchful an eye, will never bestir themselves to help the onward progress. T. them antiquity is synonymous with wisdom and every improvement is a dangerous innovation — *History of Civilization* England by H. T. Buckle London 1881 Vol. 2 p. 595

MEDICAL AND SANITARY REPORTS FROM BRITISH COLONIES, PROTECTORATES AND DEPENDENCIES FOR THE YEAR 1937

[NINTH ANNUAL ISSUE]

Summarized by P. GRANVILLE EDGE.

WEST AFRICA

COLONY AND PROTECTORATE OF NIGERIA (1937)

The Colony and Protectorate of Nigeria is the largest of the British West African possessions its approximate area including the area of the Cameroons under British Mandate being 372 674 sq miles, or more than three times that of the United Kingdom. It is bounded on the west and north by French territories, on the north-east by Lake Chad on the east by the Cameroons and on the south by the Gulf of Guinea.

Vital Statistics—The townships of Aba and Enugu are now registration areas and together with Lagos and Ebutte Metta in the Colony Calabar Port Harcourt and Kano in the Protectorate are the only areas in Nigeria where registration is compulsory (see this *Bulletin* 1938 Supp p 19*) Attempts are being made to record births and deaths in several areas under Native Administration control but in many cases the figures are at present of little value. In this connexion the Report observes: The movement of population between the towns is so great and the growth of the larger towns so rapid that many of the residents do not belong by birth [to such towns?] and the age distribution consequently shows a peak in the middle years. In addition people return to their birthplaces if possible to give birth to their children and also when sickness overtakes them [Query: Would it not be possible under the regulations governing registration to provide for the transfer of records of births to areas of habitual residence of parents of newly-born children and deaths to place of habitual residence of decedents?]

Population figures for Nigeria as a whole are not given in the Report under review (see this *Bulletin* 1938 Supp p 19*)

The relevant facts assembled from the registration areas mentioned above read as follows:—

Registration Area	Estimated Population	Birth Rate	Death Rate	Infant Mortality Rate
<i>The Colony</i>				
†Lagos and Ebutte Metta	155 800	22.9	23.3	130
Enugu	14,541	20.0	19.7	312
Aba	9 152	31.5	18.8	187
<i>The Protectorate</i>				
Port Harcourt	20 000	10.6	9.9	235
Kano	8 710	12.6	25.0	180
Calabar	18,000	27.2	20.2	67
Ijebu Province	333 000	36.0	27.0	—

† In a separate Report, the *Annual Report of the Medical Officer of Health Lagos* detailed information is supplied.

In Lagos 88.6 per cent. of all deaths are certified by medical practitioners in Port Harcourt 73 per cent. in Aba 61 per cent. in Kano 59 per cent. in Enugu 49 per cent. and in Calabar 38 per cent.

At the Government Laboratory Lagos, an investigation was commenced into the causes of death in African children up to three years of age. Post mortem examination was made of all children whose deaths were not medically certified. The investigation promises to yield useful information with regard to the incidence of malaria and the pneumonias with respect to age, climatic conditions, etc.

European Officials resident numbered 2,131 with an average number resident of 1,520. Of these 106 were invalided and 6 died. Twenty-four per cent. of the cases of invaliding were due to *neurasthenia*, 7.6 per cent. to *asthenia* and 5.7 per cent. to *malaria*. Of the deaths 2 were due to *yellow fever* and 1 to *blackwater fever*.

Twenty-nine deaths were recorded among non-native non-officials and of these 4 were due to *yellow fever*, 4 to *malaria* and 1 to *blackwater fever*.

The number of African Officials resident is not stated, but 18 were invalided and 32 died during the year. The principal causes of invaliding were *defective vision* 16 per cent. and *neurasthenia* 11 per cent. and of the deaths 20 per cent. were due to *nephritis*, 20 per cent. to *pneumonia* and 10 per cent. to *pulmonary tuberculosis*.

The average daily strength of the Nigeria Regiment (African R W A F F) was 3,082. Of these 23 were invalided and 21 died. The average daily strength of the Nigeria Police (Africans) was 3,429. 25 were invalided and 42 died.

Maternity and Child Welfare Work—Activities continued to expand (see this Bulletin 1938 Supp. p. 20*). A total of 2,331 normal deliveries was recorded in Government and Native Administration hospitals and maternity centres as compared with 1,893 in the preceding year. Infant Welfare Clinics continued to function at a number of medical stations. In Lagos 188 clinics were held during the year and 3,697 infants recorded 8,806 attendances. Health Visitors paid 41,836 domiciliary visits during the year. According to the Report under review the various Religious Missions maintained 71 Maternity and Child Welfare Centres, 39 of these being established in the Northern Provinces. [This suggests some curtailment of these activities for in the 1936 Report there were 116 such centres with 77 of them in the Northern Provinces.]

At the end of the year there were 83 midwives registered under the Midwives Ordinance, 35 of them in possession of the Grade I Certificate. Four certificates as Grade I midwives, and 23 as Grade II were granted during 1937.

School Hygiene—There is no mention of any organized School Medical Service (see this Bulletin 1938, Supp. p. 21*). Close co-operation is maintained with the Department of Education in connexion with the hygiene of schools and health education. In Lagos a school clinic is maintained and in the Northern Provinces the periodical examination of school-children has been carried out in certain areas, but no details of these activities are supplied. Conditions are said to vary between wide limits in the various schools reported upon by Medical Officers. The following extracts relate to two schools in the Northern Provinces.

Medical Officer Idah Kabba Province reports.—‘The only important school in the District is at Dekina. The general lay-out is satisfactory. It is a fine example of what can be done by a willing body of men. Any minor complaints are dealt with at the Native Administration Dispensary situated close at hand. The school consists of well fitted and lighted buildings. The whole area is a sanitary delight.’

Medical Officer Pankshin Plateau Province observes — There are two elementary schools and about a dozen Mission schools. Latrines and other sanitary facilities are the exception. The latrines at Pankshin School are in ruins.

Public Health Sanitation etc—The sanctioned establishment of the Department was increased by 5 medical Officers of Health, 2 African Medical Officers, 2 Nursing Sisters and 7 Sanitary Superintendents while additions were also made to subordinate personnel grades. These increases enabled the posting of a Medical Officer of Health to the Cameroons and the provision of personnel for the sanitary control of aerodromes in Nigeria. *Anti malarial* measures continued along lines previously described (see this *Bulletin* 1938 Supp p 21*-22*). Larvicidal work against *A. gambiae* and *A. furestus* was carried out to the limit of available funds. *Yellow fever* control work demanded and received special attention. The routine inspection of premises for the control of domestic mosquito-breeding was continued and in certain areas a campaign was carried out against water bearing plants which are potential mosquito-breeding foci. The anti-mosquito measures carried out by the Lagos Town Council were particularly thorough and praiseworthy; the larval index dropped from 9.8 in June to 0.7 in August. Supplementing previous descriptions of methods of *sewage disposal* (see this *Bulletin* 1934 Supp p 5*, 1935 Supp p 6*, 1936 Supp p 10*, 1937 Supp p 15* and 1938 Supp p 22*) the Report under review observes that the use of latrines has continued to advance gradually but that a large proportion of the population of Nigeria continue to pollute the ground by indiscriminate defaecation. Tribes living in the vicinity of creeks, lagoons etc. have continued to make use of such waters for the direct disposal of night soil. In some places latrines built over the water are in use but in limited areas the practice results in the accumulation of offensive waste matter. The *salga* or cesspit is in common use in many towns and villages, especially in Northern Nigeria. Bore-hole latrines on the other hand have not been tried on a sufficiently wide scale though in many areas ground conditions are suitable. Pipe-borne water supplies provided by Government and Native Administrations are available in a number of areas in both the Northern and Southern Provinces but not in all cases have supplies been submitted to purification treatment. It was decided that for the future all pipe-borne public supplies constructed by Government should be potable and unlikely to be the carrier of any form of disease. In the Northern Provinces the Geological Department provided additional wells in the Emirates of Hadzima, Katsina, Katagum and Visau.

With regard to *labour conditions* it is noted that as a result of discussions an extensive building programme has been drawn up

At the various Laboratories in Nigeria (see *Scientific* below) 14,245 blood films were examined for the presence of malaria parasites: positive findings recorded were *P. falciparum* 3,853 *P. malariae* 14, and *P. vivax* 3. Crescents were present in 24 films examined.

Of *Yellow fever* 18 cases with 11 deaths were recorded among Europeans and 10 cases with 4 deaths among Africans. The first outbreak occurred in May at an American Mission at Ogbomoso in Oyo Province and the disease appeared later in 12 other centres in the Northern and Southern Provinces. It is of interest to note that of the 18 European cases 11 occurred on Mission compounds where Europeans and Africans live in close proximity: 3 occurred in European officials (one wife) on tour where no adequate separation of rest-houses from native habitations is normally found, and the remaining 4 were associated with residence in commercial compounds. No infection has ever been reported to have taken place in a residential area.

A high *Aedes* index was always associated with the outbreaks, but it is noteworthy that the larger towns, where mosquito control measures are vigorously applied, remained free from the disease (see also *Public Health* above). An unusually large number of protection tests and tissue section examinations were performed by the Laboratory Service for purposes of diagnosis. Protective inoculation with a vaccine supplied by the Wellcome Bureau, of persons likely to be exposed to the risk of yellow fever was undertaken experimentally in Lagos, and investigations were made into cases of post inoculation jaundice. A notice issued by the Department and widely circulated urged all Europeans to undergo protective inoculation: the response was very good.

Smallpox was again prevalent and particularly severe in the Northern Provinces as may be gathered from the following summary of reported cases and deaths:—

	Cases	Deaths
The Colony	18	—
Southern Provinces	564	85
Northern Provinces	3 085	436

Routine vaccination was continued by Government and Native Administration Vaccinators and intensive campaigns were organized in epidemic areas: altogether 38,336 vaccinations were performed in the Colony 395,324 in the Southern Provinces and 477,962 in the Northern Provinces. After several years of experimental work the Laboratory Service has perfected its methods for the preparation of a satisfactory vaccinia vaccine, and has entered on the preliminary stages of large-scale production.

No case of *plague* human or rodent was notified during the year. In December an outbreak of a disease resembling bubonic plague was reported north of Zinder (in the French Colony of the Niger). Immediate steps were taken to prevent entry of the infection into the Northern Provinces but later investigations failed to prove that the outbreak was due to plague.

An extensive epidemic of *cerebrospinal fever* of unusual severity raged in the north of Nigeria from January to May and was responsible

for 2,823 deaths in a total of known cases of 3,452. It is doubtful whether all cases were reported while on the other hand deaths due to other causes may have been attributed to the disease during the period of the outbreak. The usual control measures were applied and with the arrival of the rains the number of cases rapidly diminished. Serum tests made after recovery proved the occurrence of *typhus fever* in two Europeans in Kano and one in Gboko (Benue Province).

The text of the Report mentions only 12 reported cases of *enteric fever* with 5 deaths whereas hospital returns show 23 cases of typhoid 2 of paratyphoid A 3 of paratyphoid B and 2 cases in which the type of infection is not defined of these totals 22 cases of typhoid occurred among non Europeans with 4 deaths. At the Laboratory 67 sera were tested 19 were positive and 8 doubtful. No details as to types of organism isolated are supplied.

In and out patients treated for *dysentery* totalled 6,337 with 147 deaths distributed as follows —

	Amoebic	Bacillary	Unspecified	Deaths
Europeans	66	15	30	—
Non Europeans	3,222	113	2,891	147

At the various Laboratories where 12,634 specimens of faeces were examined 558 were found to contain *E. histolytica*. In addition 183 faecal specimens were cultured and the following organisms isolated *B. dysenteriae* Flexner 46 times Shiga 9 Schmitz 2 and Newcastle 1.

Trypanosomiasis—Treatment alone or treatment combined with minor measures of tsetse control have failed to stem the advance of the disease into new areas and the situation in the Northern Territories has for some years been the cause of much anxiety. To deal with the problem the Deputy Director of the Sleeping Sickness Service prepared a comprehensive scheme. In an Appendix to the Report under review this scheme is described in detail but for the purposes of the present summary it will suffice to say that the plan provides for the recruitment of additional personnel the removal of hamlets and re-settlement of the people in clean or protected areas where seed land wells and other necessities will be provided for the settlers. *The Sleeping Sickness Ordinance* 1937 was enacted early in the year to provide powers to enable the scheme to be put into operation the Colonial Development Fund is providing £19,000 per annum for the work on the understanding that the Nigeria Government provides an additional annual contribution of £11,000. By October 1937 most of the European personnel had been recruited.

Meanwhile during 1937 five Sleeping Sickness Teams continued to carry on with the usual field work. 447,358 people were examined 29,011 were found to be infected and 28,426 had completed treatment by the end of the year.

The Special Sleeping Sickness Scheme and Annual Report should be read in its entirety its contents describe such matters as research work (much restricted owing to shortage of staff) entomological investigations therapeutic measures and control work the re-settlement schemes etc.

Tuberculosis—Hospital returns show there were 17 European cases of *pulmonary tuberculosis* with 1 death and 3 cases of other forms of the disease with 1 death among non-Europeans there were 1 041 cases of the pulmonary form of the disease with 177 deaths and 530 cases of other forms of tuberculosis with 33 deaths. In Lagos alone 246 deaths were ascribed to tuberculosis and of these 173 were pulmonary. Though the disease has been added to the list of compulsory notifiable diseases (see this *Bulletin* 1838 Supp. p. 26*) no mention of the numbers of cases reported during 1837 is made. Plans have been made for the erection of a small tuberculosis ward at Yaba a suburb of Lagos.

At the Laboratory work was continued on the study of types of strains of the tubercle bacillus isolated from varying clinical types of cases. Seventeen strains were forwarded to Dr A. S. GRIFFITH who typed them as follows, *Eurotic human* 8 *Dysotic human* 10 and *Bovine* 1. Samples of sputum examined numbered 1,834 and of these 281 were positive with *Mycobacterium tuberculosis*.

The Report observes that *pneumonia* "may be roughly calculated to account for 25-33 per cent of all native deaths." In- and out-patients (non-European) treated at hospitals for this cause totalled 3 186 and of these 841 died. There were also 50 624 non-European cases of *bronchitis* with 87 deaths.

Of *helminthic* diseases it is said that *ascariasis* is more common in the Southern Provinces and *taeniasis* in the Northern Provinces. The following figures appear in the hospital returns of in- and out-patients of cases dealt with during the year —

Item	Europeans	Non-Europeans
Ascariasis	10	26,170
Taeniasis	28	6,823
Ankylostomiasis	6	2 251
Dracontiasis	1	2,543
Filaria (F. bancrofti)	1	—
(Leech)	39	736
Schistosomiasis (haematobium)	1	1 167
(malinensis)	2	314

The relative incidence of *helminthic* infestation in the Municipal Area of Lagos may be gathered from the fact that among 4,531 faecal specimens examined at the Laboratory the ova of *Ascaris* were found in 2,588 *Trichuris* 1,995 *Ancylostoma* 1 754 *S. mansoni* 30, and *S. haematobium* 2 while among 4 401 specimens of urine *S. haematobium* was found in 178 cases. Our Station Laboratories reported the examination of 8 153 specimens of stools, and among these the ova of *Ancylostoma* were found in 3,305 *Trichuris* 1,281 *Ascaris* 927 and *S. mansoni* 85 among 8 473 specimens of urine *S. haematobium* was found in 414.

Leprosy—In the Northern Provinces there are 11 and in the Southern Provinces 8, *Leprosy Settlements* supported by Native Administrations. The policy of handing over the management of the Native Administrations Settlements to Medical Missions was continued approximately 5 673 lepers are resident in the various settlements.

A number of leprosy surveys were made by the Superintendents of certain settlements, and by the British Empire Leprosy Relief Association doctors while anti leprosy work is gradually being developed along the lines recommended by Dr Muir.

Venereal Diseases—The numbers of patients treated for *sypilis* and *gonorrhoea* in hospitals and dispensaries were 19 155 and 17 074 respectively. there were also 1 482 cases of *soft chancre* and 621 of *venereal bubo*. Among 3 569 samples of serum submitted to Kahn test at the Lagos Laboratory 1 491 gave positive reactions and among 275 smears 71 were positive with *N gonorrhoeae*.

Yaws is one of the most prevalent diseases in the Eastern part of the Southern Provinces and attains its highest incidence in the Cameroons where in villages remote from medical centres it chiefly affects children in the 2-5 age-group though its after-effects often persist throughout life. It is said that the employment of village *chindas* (see this *Bulletin* 1937 Supp. p. 19*) to administer injections has done little if anything to reduce the incidence of the disease. During the year an Ordinance was introduced amending the Medical Practitioners and Dentists Ordinance to regularize the practice of the administration of injections (for *sypilis* yaws sleeping sickness etc.) by unqualified persons. this Ordinance empowers the Director of Medical Services to license suitable persons to administer injections. During the year 90 225 persons were treated at hospitals and dispensaries.

Eighteen non Europeans received hospital treatment for *rabies* and 2 died but in addition 380 persons were given specific treatment for exposure to *rabies* infection. The dog was the infecting animal in all cases but one where the patient had been bitten by a cat. At the Laboratory out of 66 brains examined 33 were positive with *Neeri* bodies—32 dogs and 1 cat.

Ulcers were responsible for the treatment of 57,500 non European patients at hospitals and dispensaries, *rheumatism* for 42,367 and *eye diseases* for 19 561.

Scientific—Under this heading can be included a reference to the year's work at the Schools of Medicine and Pharmacy which forms the subject of a special report in the Annual Report under review. *The School of Medicine Yaba* provides a four years course of training leading to the Certificate of Medical Assistant. For the various examinations in 1937 the following results were recorded —

Examination	Medical Assistant's Certificates		Diploma Examination	
	Candidates	Successful	Candidates	Successful
January Section (i)	3	3	—	—
Section (ii)	15	7	—	—
June Section (i)	3	3	—	—
December	—	—	6 All	referred

Professor W. W. JAMESON, Dean of the London School of Hygiene and Tropical Medicine visited the School in November and formally opened the new physiology block which will accommodate 18 students.

At the *School of Pharmacy* at the beginning of the year there were 19 students and in April 13 new students were admitted 2 of whom were women. One student passed the Dispenser's Qualifying Examination Part I four Part II and 12 the Chemists' and Druggists' Examination.

During 1937 the Laboratory Service consisted of (a) The Office and Laboratory of the Senior Pathologist at Yaba (b) A Bacteriological Unit in charge of a Pathologist at Yaba (c) The Laboratory of the African Hospital Lagos in charge of a Pathologist (d) Clinical Laboratories at six centres five of them staffed by African Laboratory Assistants.

The Report of the Laboratory Service appears as an Appendix to the Annual Report under review. The principal specimens received and findings recorded have already been the subject of brief reference in the preceding notes under such headings as *yellow fever*, *tuberculosis*, *smallpox* etc. Another piece of interesting work is worthy of mention.

Having regard to the theory outlined by F. W. CLEMENTS in the *Medical Journal of Australia* that the mouth is the source of origin of the spirochaetes and fusiform bacilli found in tropical ulcers and abrasions may arise through the accidental inoculation of abrasions with expectorated material smeared from the gums of 58 labourers in Lagos were examined. In 43 cases the smears were found to harbour numerous spirochaetes and fusiform bacilli, there being no evidence of pyorrhoea or other infection of teeth or gums. Material from the gums of four heavily infected labourers were inoculated with nutrient broth and 7 African volunteers were pooled, diluted the mixture. In every case small ulcers resulted but the spirochaetes and fusiform bacilli disappeared in the course of a few days and no lesion of the characteristic tropical ulcer type resulted. The conclusion finally reached was one of doubt that the source of tropical ulcer infections in Nigeria is oral.

Financial.—Actual expenditure on Medical Services in Nigeria during 1937-38 amounted to £462,630.

GOLD COAST COLONY (1937)

The Gold Coast Colony with Ashanti, the Protected Northern Territories and Togoland under British Mandate is situated on the Gulf of Guinea. It is bounded on the west by the French colony of the Ivory Coast, on the east by the French Mandated Togoland, on the north by the colony of the Upper Volta and on the south by the sea. The area of the Colony is 23,937 sq miles, of Ashanti 24,379 of the Northern Territories 50,486 and Togoland 13,041 the total being 91,843 sq miles.

Vital Statistics.—The estimated population figures for the middle of the year under review read as follows—

Item	Gold Coast and Dependencies	Togoland	Totals
Africans	3 340,581	359 754	3 700,335
Non Africans	3 139	43	3 182
Totals	3 343 720	359 797	3 703,517

[With regard to the figures for Non Africans (3 182) in another section of the Report the resident European population is given as 4 791 and in yet another place as 3 890]

For the 35 established registration areas (see this *Bulletin* 1938 Supp p 29*) the relevant vital facts read as follows —

Mid Year Population	Registered Births	Birth Rate	Registered Deaths	Death Rate
333 159	11,234	33.7	8 431	25.3

In these areas birth rates range from 9.7 to 78.5 per 1 000 and death rates from 12.7 to 70.8 per 1 000. The averages for some of these well-sanitated registration centres do not reflect the health condition of the resident population in those areas for they are affected to no little extent by conditions prevailing in poorly sanitated areas surrounding them. Furthermore mortality rates are greatly influenced by the high mortality rate characterizing the 25-45 age-group of immigrant labourers this group usually provides in a population healthy male adults in the highest productive stages of life.

The General European population in 1937 totalled 3,890 persons and of these 100 were invalided and 25 died during the year.

European Officials resident numbered 901 with an average number resident of 632. Forty-eight were invalided and 7 died. Of the invalidings 12 were due to purely tropical conditions and of the deaths 1 only (yellow fever).

African Officials resident numbered 3,962 with an average number resident of 3 750. Within this group 22 invalidings and 26 deaths were recorded—6 of the deaths due to yellow fever.

Maternity and Child Welfare Work—The volume of work dealt with at established centres may be summarized as below (p.28*)

It must be remembered that in addition to provision made at the Accra and Kumasi centres welfare activities are carried out as part of the routine services provided at all Government Hospitals and Dispensaries. These important services are apt to be overlooked and in this connexion it may be mentioned that 6 900 cases of children alone were dealt with during the year at Out patient Departments.

During the year under review 647 patients were treated in the maternity wards of the Princess Marie Louise Welfare Centre at Accra and 522 in the welfare centre at Kumasi.

Nine midwives and 20 subsidized midwives figure on the staff of the Health Branch and these women conducted 2,554 deliveries. The local native midwife is rapidly losing ground now that more trained midwives are becoming available and as the services of the latter are becoming increasingly appreciated. The sphere of usefulness of these

women could be greatly extended if Native Administrations could be persuaded to provide the cost of subsidies for midwives working in their respective areas

Amedrope (Bremen Mission)	19	1,332
Totals	993	86,800

The usual *Annual Report of the Maternity Hospital Accra*, appears as an Appendix to the Report under review and describes the year's work in considerable detail. Owing to steadily increasing demands there is need for a new Out-patient Block, a larger Normal Labour Ward, and extensions to the Isolation and Ante-Natal Wards. Of the 1,376 patients admitted during the year 642 were labour cases and 553 women were admitted for ante-natal treatment. 838 live births, 73 infant deaths and 35 maternal deaths were recorded. Among out-patients there were 3,590 ante-natal and 963 post-natal cases.

At the *Maternity Training School* the increasing number of applicants seeking training indicates that midwifery as a career for the African educated young woman maintains its popularity. Under training during the year were 6 second Division Nurses, 3 Nurses-in-Training, 24 Pupil-midwives and 18 Probationers commenced their studies. Eleven midwives received the Certificate of the Central Midwives Board.

School Hygiene—No school service in the true sense exists and there is little if anything to add to former commentaries (see this *Bulletin* 1936 Supp. p. 18*, 1937 Supp. p. 22* and 1938 Supp. pp. 30*-31). Hygiene continues to be taught in all Gold Coast schools and great weight is attached to this subject on visits of inspection by officers of the Education Department. It is felt that much valuable information is being lost through the failure to establish a regular School Medical Service, but shortage of staff makes this impossible at present.

Public Health Sanitation etc.—The improvement in the general health recorded during 1936 (see this *Bulletin* 1938 Supp. p. 31) suffered a set-back during the year under review. Increased mortalities due to non-tuberculous diseases of the respiratory system and diseases

of the intestinal tract (influenced by abnormal drought conditions in some areas) were mainly responsible. Anti-malarial activities continued to be carried out to the limit of funds and staff available and most stations report progress in this field of work. It is pointed out that in many areas the greater part of funds and labour are required for the maintenance of existing drainage systems. With regard to anti-yellow fever measures (see this Bulletin 1938 Supp pp 34-35) it is stated that satisfactory mosquito control over rural areas is not possible large areas are closed books—local outbreaks may occur but not be reported by responsible Chiefs. The value of protective inoculation to Europeans of all classes is continually emphasized.

Under the heading of sewage disposal it is observed that in the Northern Territories a simple type of septic tank latrine has been evolved for use in rural areas. The water-carriage method of drawn and when composted with organic household refuse the final has a high manurial value. The water-carriage septic tank method of disposal from bungalow properties steadily advances but the final disposal of the effluent gives rise to anxiety in some areas. The central congested areas of the larger centres of population call for the provision of water-carriage sewer borne systems but water is not yet available in sufficient quantity to permit consideration of such schemes. Large rural areas are without sanitary and adequate pit latrine accommodation nor do means exist of bringing pressure to bear upon Chiefs that such provision should be made. Meanwhile until the decision is taken as to whether indirect rule or direct rule methods shall govern sanitation standards decline village surroundings continue to be excreta soaked and anxieties increase.

The investigations of the Public Works and Geological Departments into the water supplies in the Northern Territories have already resulted in the establishment of supplies in certain seriously affected areas. Improvements to the water supplies in various villages in Ashanti and the Colony were carried out during the year and work was commenced at the Accra Water works on the installation of additional plant capable of increasing output to 2 000 000 gallons.

Sanitation in the Mining Areas is discussed in forming an Appendix a Report contributed by Dr H P FOWLER and forming an Appendix to the Annual Report under review. The population concerned comprises 601 Europeans and 20 351 African labourers. In areas actually controlled by mining companies good progress is reported—there is continued improvement in the type of latrine employed and septic tank installations are being introduced in increasing numbers in European bungalows. Many mines have piped water supplies to their mine villages. But in districts surrounding the above areas masses of insanitary hovels have sprung up and here until new legislation can be enforced little improvement can be expected. In the section where Labour Conditions are discussed it is observed that large influx of potential labour into the Gold Coast from neighbouring territories continued over 38 000 persons were disinfecting at the station near Kumasi as against 22 978 in 1936. Many of the newly arrived immigrant labourers are in poor physical condition and a considerable percentage of them diseased (see also this Bulletin 1938 Supp p 32*)

Progress in connexion with *housing and town planning* schemes in most of the larger centres of population is reported. On the other hand there is urgent need for attention to be devoted to the clearance of slum areas in some towns. In Accra, it is estimated that one-tenth of the people live under insanitary and overcrowded conditions.

Food in relation to Health and Disease is discussed and mention made of the unbalanced nature of the average Gold Coast dietary (see this *Bulletin* 1938 Supp. p. 32*). Foodstuffs, markets, bakeries etc., continue to be inspected regularly in centres where Health Staffs are stationed.

The Central School for the *training of Sanitary Inspectors* continued to function throughout the year with an average of 20 men in training. *Village overseers* continue to be trained at Kumasi. It is hoped to establish a school for Native Administration village overseers at Tamale (Northern Territories).

Recommendations for future work include the provision of water supplies for certain districts, water borne sewage disposal for Accra and Kumasi, slum clearance in Accra, provision of infectious diseases hospital and quarantine station at Takoradi, and staff increases of one Assistant Director of Health, two Sanitary Superintendents, and three Health Visitors.

Port Health Work—Accra (town and port) was placed in quarantine on two occasions during the year owing to outbreaks of yellow fever. At Accra 614 ships entered and 7 147 immigrants and deck passengers were appropriately dealt with. At Takoradi ships entering numbered 784 and immigrants and deck passengers 8,929. No plague infected rat was caught at any of the Gold Coast ports during the year. Work proceeds on the *anti-malarial aerodromes* at Accra and Takoradi. The Accra aerodrome is in regular use but so far passenger traffic has been slight.

Hospitals, Dispensaries, etc.—Work on a new hospital at Cape Coast was commenced during the year and progress is reported in connexion with the new Infectious Diseases Block in course of construction at the Gold Coast Hospital, Accra. The distribution of the 7 European and 41 African hospitals and bed accommodation at these institutions, and Dispensaries established throughout the Gold Coast is as follows:—

Locality	European Hospitals		African Hospitals		Dispensaries Number of
	Number	Beds	Number	Beds	
Eastern Province	1	18	21	491	13
Central	1	6	8	148	7
Western	2	77	4	119	6
Ashanti	1	12	4	211	4
Northern Territories	1	6	6	145	8
Total d	—	—	2	41	3
Contagious Diseases Hospitals	6	68	32	1 165	41
	1	4	9	168	—
Totals	7	72	41	1,321	41

29* GOLD COAST COLONY (1937)

At these institutions 28 237 in-patients were treated 2 247 died and 301 855 out patient cases were dealt with For three centres only are in patients classified with distinction as to race viz —

	In-patients Treated		
	Europeans	Africans	Totals
	408 473 241	3 073 1 612 3 371	3 481 2 085 3 612

Accra
Sekondi and Takoradi
Kumasi

In addition to the 41 Dispensaries mentioned above 5 more are in course of construction at 21 of the dispensaries conducted by African staffs 52 078 out patients were treated during the year

In Mining Areas seven of the many Companies have their own full time Medical Officers with satisfactory medical and sanitary personnel on six of the mines adequate hospital accommodation is provided for African employees and five of them provide separate hospital accommodation for Europeans. The mines without resident Medical Officers have fairly well equipped dispensaries and dressing stations

Welfare work undertaken by Missions has been mentioned in the preceding notes it remains to say that the only hospital (General?) maintained by a Mission is that of the Basel Mission Hospital at Agogo in Ashanti. At this centre work steadily increases year by year during the year under review 1 408 in-patients and 7 368 out patients were treated.

The scheme of Government Medical Scholarships introduced in 1931 for the purpose of enabling suitable Africans to qualify in medicine in the United Kingdom continued to function A scholar was selected during 1937 and there are now two students engaged on preliminary studies at Achumota College and three making satisfactory progress in England. In April 1937 the Secretary of State approved the institution of Government Dental Scholarships in the interests of suitable Africans. Two scholars will be selected in 1938

The text of the Annual Report under review provides an account of the factors affecting the public health and discussion of the principal items of morbidity experience during 1937 The notes which follow briefly summarize some of the more important references to these matters.

Malaria continues to be the most important factor adversely affecting the public health infection can be considered almost universal and every pathological condition throughout life is complicated by it During 1937 there was a marked increase in the number of cases treated 30 581 as against 25 130 in the preceding year Of the 30 581 cases 2 483 were treated as in-patients and 76 of them died among them were 14 cases of blackwater fever with 5 deaths. The distribution of types of infection among all cases recorded was benign tertian 443 quartan 67 subtertian 18 685 malarial cachexia 269 blackwater fever 20 and unclassified 11 092 cases The scheme for the distribution of quinine through the Post Offices

continued to function with conspicuous success sales increased by approximately 100 per cent (see this *Bulletin* 1937 Supp p 25*) At the Accra Laboratory where 4 684 blood films were examined, 1 786 were found to contain malaria parasites types of plasmodium are not differentiated

The year under review was the worst yellow fever year since 1927 The virulence of the infection was unusually severe 69 deaths occurring amongst the 75 cases recorded most of the Africans who died did so on or about the fifth day of the disease In the area chiefly affected—the southern portion of the Eastern Province to the north and north-east of Accra—the rains were deficient and late this led to extensive storage of water invariably unprotected, in houses in the backwarrural districts Satisfactory control in such areas is not at present possible Of the cases and deaths recorded 72 cases and 67 deaths occurred in the Colony these comprised one fatal European case four fatal Syrian cases and the remainder were Africans Three cases and two deaths occurred in the Northern Territories one being a fatal European case

In centres where control measures were possible the usual house-to-house inspections were carried out over 2,600 000 visits were made to premises and an average Aedes index of 0.5 recorded.

The Report of the Senior Pathologist gives a detailed account of the pathological findings in the 67 fatal cases recorded in the Colony a noteworthy feature was the frequency with which intranuclear cell inclusions were seen A number of photomicrographs in black and white and in colour of livers from cases of yellow fever are reproduced The possibility of an extension of yellow fever beyond the West African endemic area by means of the rapidly increasing number of trade land routes is discussed it is a matter of economic difficulty for the machinery of prevention to keep pace with these rapid developments The value and importance of protective inoculation is emphasized

No case of cholera or of relapsing fever was recorded. With regard to the latter disease it is noted that 22,378 immigrants were dealt with at the de-lousing station near Kumasi Smallpox was responsible for 43 cases with 2 deaths 343 193 persons were vaccinated While no case of plague was reported, nor were any rats bacteriologically examined found to be infected with *P. pestis* the disease constitutes a direct threat and may force an entry into the Gold Coast as it has done in the past Much rat-proofing remains to be done and the slum areas in the vicinity of the port at Accra demand urgent attention. One fatal case of cerebrospinal meningitis is mentioned

Cases of typhosomiasis treated in hospital dispensaries and camps during the year numbered 5 162 with 156 deaths, while 175 deaths were attributed to this cause in the whole of the Gold Coast The most seriously affected areas were the north-eastern and north-western parts of the Northern Territories where 2 750 and 1 423 cases respectively were recorded The survey mentioned in the 1936 Report (see this *Bulletin* 1936, Supp p 35) was organized and work commenced during the latter half of the year the results of this investigation will be presented in due course At the Accra Laboratory among 4 684 blood films examined 12 were found to contain trypanosomes

While *enteric fever* does not loom largely as a killing disease it is believed to be much more common than recorded cases and deaths would suggest. During the year 129 cases were reported and 29 deaths were registered as due to this cause. Hospital in patients numbered 100 distributed as to 85 typhoid 8 paratyphoid A 1 paratyphoid C and 6 undefined cases. The Report observes that incidence is likely to increase in the larger population centres where insanitary conservancy systems and unwholesome drainage systems contribute to the spread of infection. Diseases of the dysentery diarrhoea and enteritis group moved from third to second place in the list of killing diseases largely due to the drought conditions experienced in many areas during the year. Here again incidence is highest in areas where insanitary conservancy conditions and questionable water supplies are found. It is said that as a rule the amoebic form of the disease is twice as common as the bacillary. Among 487 hospital in patients (57 died) 294 were amoebic cases 133 were bacillary and 1623 out patients. Among 2,571 stools microscopically examined at the Laboratory E histolytica were found 822 221 and 580 respectively. Among 2,571 stools microscopically examined at the Laboratory E histolytica were found 68 times and among 333 faecal specimens bacteriologically examined, *Bact dysenteriae* Flexner was isolated 40 times Shiga 3 times and Schmitz 7 times. Hospital in patients treated for diarrhoea and enteritis numbered 510 (49 deaths) and out patients 5,582 of the latter 2,314 were children under two years of age. According to findings recorded at the Laboratory the serum of 3-4 per cent of Africans and Europeans contained agglutinins for *Bact. enteritidis*.

As a single disease entity *tuberculosis* heads the list of fatal diseases while the *pulmonary* form claims over 90 per cent of the total deaths due to all forms of tuberculosis. Approximately 49 per cent of all deaths ascribed to pulmonary tuberculosis occurred in the male 25-45 age-group—this group comprising practically the whole wave of immigrant labour (see also *Vital Statistics* above and this Bulletin 1938 Supp. p. 36*). The deep-mining industry certainly affects the picture. The mine-worker is free to come and go as he pleases in becoming aware of his condition he usually sets out for his home and in most instances has ceased to be a miner before death supervenes. The effects of underground mining on the health of Africans is briefly referred to in a special report contributed by Dr H. P. FOWLER, who observes that at present reliable data relating to the incidence of tuberculosis and silicosis are not available. An investigation is to be undertaken by expert officers who will have a radiological unit at their disposal. Among 477 hospital in patient cases of all forms of tuberculosis with 222 deaths 413 of the cases and 207 of the deaths were due to the pulmonary form of the disease. Among 908 out patient cases 783 were cases of pneumonia were treated and 1,394 deaths under review 2,114 cases of pneumonia were treated and 1,394 deaths were registered as due to this cause. Here again males in the vulnerable 20-45 age-group contribute the largest number of cases and deaths. Bronchitis was responsible for 399 in-patient and 14,793 out patient cases.

Helminthic Diseases—The following figures taken from the Hospital Returns summarize cases dealt with during 1937 —

Diseases	In-patients	Hospital Deaths	Out-patients
Taeniasis	95	2	2,315
Ascariasis	148	2	1,532
Ancylostomiasis	434	18	1,037
Dracontiasis	227	1	973
Schistosomiasis	143	10	710

Ancylostomiasis and *ascariasis* are common in rural areas where sanitary latrine accommodation is lacking *taeniasis* in areas where fuel shortage makes the cooking of meat adequately a difficult matter *Dracontiasis* is common outside the larger population centres in areas where clean water supplies are lacking *Schistosomiasis* is said to be more widely distributed than is generally supposed the condition is frequently ignored by the sufferer and only discovered during a general routine medical examination

Leprosy.—At the Leper Settlements at Ho Kumasi, Yendi, Sekondi, and Accra, 572 inmates were under treatment of this total 410 patients were treated at the Ho Settlement It is generally believed that there are some 7,500 lepers in the Gold Coast incidence is lowest in the South and increases progressively from South to North. An account of the year's work at the Ho Leper Settlement is contributed by Dr G L ALEXANDER Medical Officer in Charge During the year 64 new cases were admitted, 38 old cases re-admitted, 39 absconded, 15 died, and at the end of the year there remained 268 patients under treatment. Two out of four nasal smears examined at the Laboratory were positive with *Mycro lepro*

General diseases.—The following Table summarizes cases dealt with during the year —

Disease	In patients	Out patients
Syphilis	122	734
Soft Chancres	91	898
Gonorrhoea	371	4,162
Gonorrhoea Venereum	8	9

At the Venereal Diseases Clinic of the Gold Coast Hospital, Accra new patients numbered 653 and attendances 15,439 At all centres the proportion of gonorrhoea cases exceeded those of syphilis During the year 83,684 cases of yaws were dealt with (see this *Bulletin* 1938, Supp. p. 37*) and of this total 5,220 cases were seen at Infant Welfare Centres The distribution of the disease is curious On the western side of the Northern Territories yaws was responsible for 63 per cent. of all cases seen at Bawku in the north-eastern corner of the Northern Territories only 8.5 per cent. of all cases were yaws, but further south in the villages served by the Yendi Hospital, the proportion was over 90 per cent The campaign against the disease continues.

Out of 3,095 samples of serum submitted to Wassermann test, 1,333 or 43 per cent. gave positive reactions Organisms morphologically indistinguishable from gonococci were found in 231 (46 per cent.) of 610 smears examined at the Laboratory

Scientific—The usual record of the year's routine work is supplied the more important of the specimens examined and findings recorded have already been subjects of brief mention in the preceding notes. *Research work* was mainly concerned with the yellow fever outbreak during the year—the summary notes describing the outbreak contain a reference to the Report of the Senior Pathologist in this connexion (see yellow fever above).

The *Annual Report of the Analytical Chemist* observes that 2 182 specimens of various kinds were dealt with during the year 1 595 samples being received for examination from the Customs Department. Included as *Appendices* to the *Annual Report* under review are the following reports on interesting cases—

- (a) PURCELL F. V. *Primary acute carcinomatosis of the liver*
- (b) — *Cerebello-pontine Tumour Syndrome (acoustic neuroma)*
- (c) MACRAE A. V. *Yellow Fever with Filariasis simulating an acute abdominal emergency*
- (d) — *Sub-acute Yellow Atrophy of Liver occurring during the Yellow Fever epidemic*

and in addition to the above—

- (1) The *Annual Report of the Leper Settlement* Ho
 - (2) The *Annual Report of the Maternity Hospital* Accra.
 - (3) *Annual Report (Health Branch) on the Western Province*
- particular reference to the Mining Areas.

Financial—Actual expenditure on Medical Services during 1937 amounted to £339 721 a sum which represents 12·6 per cent of the total expenditure of the Colony during the same year

SIERRA LEONE (1937)

The Colony and Protectorate of Sierra Leone has an area of nearly 28 000 sq miles a little less than that of Scotland. The sea coast is 210 miles long and extends from Kairaba on the border of French Guinea to the Mano River on the Border of the Republic of Liberia.

Vital Statistics—The system of registration organization and executive staff remain as previously described (see this *Bulletin* 1938 Supp. p 33*) no new registries were opened during 1937. Although the Colony is well served with registries for Freetown alone are data regarded as dependable in the Protectorate figures are far from complete. The recorded facts supplied by the Chief Registrar read as follows—

Area	Population	Births	Birth Rate	Deaths	Death Rate	Infant Deaths	I M R.
The Colony	104 822	2 408	22·9	2 568	24·5	593	246
Freetown	63 758	1 344	21·0	1 459	22·8	377	243
The Protectorate	1 672,058†	1 843	?	565	?	80	?

† Census figure 1931

Having regard to the difficulties attending registration efforts, Dr W P H LIGHTBODY the Chief Registrar is able to supply an admirable series of tabulations. Births deaths and infant deaths are classified with distinction as to sex for all Registration Districts in the Colony and Protectorate for Freetown deaths are classified by cause infant deaths by cause and in various age-groups.

European Officials resident numbered 227 with an average number resident of 167. Thirteen were invalided and one died. Of European non-officials there were 565 resident with an average number resident of 416. Among this group 19 were invalided and 1 died.

There were 984 African Officials resident with an average number resident of 931. thirteen were invalided and four died.

The average strength of African Troops (R.W.A.F.F.) was 375. During the year 184 men were on the sick list and 1 died. The total strength of the African Police was 271. 170 were on the sick list during the year and 1 died.

Maternity and Child Welfare Work—Steady progress was maintained in maternity services and during the year 537 cases were admitted to the Maternity Ward of the Connaught Hospital, 393 were delivered of their babies, and 5 maternal deaths were recorded. The new *Maternity Training Centre* in course of erection approaches completion.

The voluntary training of midwives continues to make satisfactory progress. 5 pupils are undergoing training and 5 obtained the C.M.B. certificate in 1937.

There were 830 new cases entered on the registers of the *Ante-natal Clinic* Freetown and 6414 attendances were recorded during the year while at the *Post-natal Clinic* 459 new cases were dealt with and 1173 attendances recorded (see also this *Bulletin* 1938 Supp p 39*). It is said the clinics in the out-stations are becoming increasingly popular.

Infant Welfare Clinics are now held three times a week at the Maternity Centre Freetown and are well attended. 511 cases were on the registers and 13060 attendances recorded. *Health Visitors* attached to the Clinic paid 9,325 visits to 782 newly-born babies.

In addition to the above services, maternity and child welfare work is carried out at the various *Mission Hospitals* with success. The work of the Princess Christian Mission Hospital (in the Colony) maintains a very high standard while at clinics at the Mission Hospitals in the Protectorate work has reached a high standard and is increasing daily.

The annual Health and Baby Week was an unqualified success.

School Hygiene—Systematic medical inspection of school-children was not possible owing to shortage of staff, but a special survey of a number of Protectorate schools was carried out during the early summer. 23 schools were visited and out of 1,806 children on the registers 1,444 were examined and individual records of age sex height weight tribe and other details inscribed. Of the total children examined 14.3 per cent of the boys and 18.5 per cent of the girls were judged to be of poor physique the majority of these under 10 years of age. Poor physical development was rarely seen in children of 14 years or over. The average spleen rate was 55.6 per cent, the rates ranging from 11.6 to 85.0 per cent. No case of scurvy beriberi, or pellagra was seen.

Public Health Sanitation etc—The health of the Colony and Protectorate during 1937 is said to have been fairly satisfactory. *Anti malarial* and *Anti Yellow Fever Measures* which for many years to come will prove a major activity of the Health Branch were continued along lines previously described. These matters are as usual discussed in the Report in great detail. Mosquito control in the Protectorate deserves more attention than it has so far received owing to lack of staff and funds but it is hoped that organized control work may be started in the near future.

Methods of *sewage disposal* remain unchanged. The question of a modern water borne sewage system for Freetown is a matter demanding the earnest consideration of Government. In the Protectorate pit latrines continue in general use it is considered that bore-hole latrines might be tried in areas where the soil is suitable. Methods of *refuse disposal* also remain as previously described. (For further descriptions see this *Bulletin* 1935 Supp p 25* and 1937 Supp p 30*.)

The various *water supplies* were maintained as usual throughout the year. The Freetown supply gives cause for considerable anxiety and has for some time shown definite signs of pollution. bacteriological examination of the water confirms this. Pending the installation of a chloramine sterilizing plant the public have been warned to boil all drinking water. The Waterworks Engineer contributes a brief report for the year under review. None of the supplies in the Protectorate can be regarded as satisfactory and many of them are inadequate as to quantity.

Housing and Town Planning conditions remain as described in this *Bulletin* 1937 Supp p 30*.

With regard to *labour conditions* housing is receiving increased attention and the general sanitary condition of the lines in the diamond mining area is said to be on the whole very satisfactory. in the alluvial gold mining areas less progress in regard to these matters can be recorded. Regulations governing the minimum basic requirements for the housing of native labour are under consideration.

The courses of *training of sanitary personnel* were continued as usual. In 1938 three British Sanitary Superintendents will be permanently stationed in the Protectorate where they will exercise a stricter control over the routine work of the African Sanitary Inspectors.

A *Health Week* was organized in all Medical Officers Stations in the Protectorate. reports indicate that these events have become increasingly popular.

Port Health Work—Increase in shipping activity is reported. 968 ships entered the port of Freetown. 1495 deck passengers and 20230 Krio boys embarked and 1798 deck passengers and 21715 Krio boys disembarked. During the year 4,373 Krio boys and 887 deck passengers were vaccinated.

The Medical Officer (Health) Freetown is at present also Port Health Officer. An additional Medical Officer for Port work is urgently needed.

Hospitals Dispensaries etc—A new European Hospital is in course of erection. An additional Protectorate-type hospital was erected at Kailahun. There was a further increase in the numbers of patients.

attending hospitals for treatment, but subsequent attendances show a falling off. Including the Lunatic Asylum Infirmary Leper Asylum and Hospital for Infectious diseases, there are 15 Government Hospitals for the accommodation of African patients.

There are 8 Government Dispensaries in the Colony and 14 in the Protectorate. 2 new dispensaries are in course of construction.

There are four Mission Hospitals subsidized by Government, and three hospitals maintained by Mining Companies.

Details of hospital accommodation patients treated, etc. during the year under review may be summarized as follows —

Hospitals	Beds	In-patients	Deaths	Out patients
1 European	14	174	4	306
15 African	854	8,273	385	115,717
8 Mission	98	1,578	7	31,894
3 Mining Companies	No details supplied			

The principal diseases treated at hospitals and dispensaries during 1937 included bronchitis 13,709 cases, malaria 10,232 (includes 11 cases of blackwater fever), rheumatism 9,497, yaws 9,312, constipation 8,649, wounds and injuries 7,770, venereal diseases 3,738 cases.

Malaria caused the deaths of one European and seven Africans and blackwater fever one European and seven African deaths also. The distribution of types of infection with distinction as to race can be summarized in the following manner —

Race	Benign tertian	Quartan	Subtertian	Cachexia	Undefined	Blackwater Fever
European	4	4	70	—	41	3
African	55	103	761	61	9,122	8

Among the above cases there were 83 European and 408 African in-patients.

Preventive measures against malaria have been the subject of brief mention in the section *Public Health* above, but it remains to add that the distribution of quinine through the agency of Political Officers and Post Offices was continued on a satisfactory basis throughout the year.

At the Laboratory where 2,550 blood films were examined, 709 were malarial infections, 193 quartan, 1 benign tertian and 37 were mixed subtertian and quartan infections.

Though many cases of yellow fever were reported in neighbouring Colonies, Sierra Leone remained free from the infection. The vigilance exercised on visiting ships, crews and passengers was of an exacting nature, and was successful in preventing introduction of the disease.

Sporadic cases of smallpox were reported but preventive measures taken early controlled the spread of the disease. In the Colony 31 cases

and 1 death in Free town 9 cases and 1 death were notified and in the Protectorate 103 non fatal cases were recorded. During the year 37,952 vaccinations were performed.

Eleven cases of *typhus fever* were reported. At the Laboratory agglutination tests were applied to 123 samples of serum 12 of them yielding titres considerable above normal. Typhus was definitely diagnosed in 10 cases seven being of the "X 19" type and three of the indeterminate or "X 2" type. The remaining two cases though agglutinating OXh to a high titre did not exhibit a clinical condition resembling typhus nor was the characteristic rise and fall of the agglutination titre observed over a period. As has been previously suggested (see this *Bulletin* 1938 Supp. p. 42*) these results tend to confirm the fact that two forms of the typhus group exist among the population.

No case of *plague cerebrospinal meningitis relapsing fever* or *rabies* was reported. During the year 3,463 rats were examined for *P. pestis* but all gave negative results. The flea index was 1.8 and the *X. cheopis* index 0.37.

Thirteen cases of *typhoid fever* were notified. 5 of the cases were imported. Hospital Returns show three European in-patient cases of typhoid and one case in which infection was undefined, and one out-patient case. Among natives there were 10 in-patient cases with 2 deaths and 7 cases among out-patients. Reported cases of *dysentery* numbered 462. One European case was treated in hospital for *amoebic dysentery* and there were 2 out-patient cases of *bacillary dysentery* and one in which the type of infection was not defined. Among African in-patients there were 75 cases of *amoebic* 2 of *bacillary dysentery* and 18 undefined cases the corresponding figures for out-patients being 179 7 and 77 respectively. At the Laboratory where 1,848 faecal specimens were examined 30 were positive with *E. histolytica* (free) and 10 with *E. histolytica* (cysts).

Tuberculosis—In one section of the Report it is stated that 2 cases were reported amongst Europeans and among Africans 182 cases with 26 deaths. The classified Hospital Returns show two European cases (one an in-patient) and among Africans a total of 197 cases. Of the latter 73 were treated as in-patients with 27 deaths 55 of the cases and 24 of the deaths being ascribed to the *pulmonary* form of the disease. Among the 124 African out-patient cases 106 were suffering from *pulmonary tuberculosis*. In Free town alone 77 cases were notified during the year but it is surmised many more people suffered from *pulmonary tuberculosis* than were notified. In Free town *tuberculosis* is now the third most important cause of death.

A marked increase in the number of cases of *avitaminosis* is reported, viz. 2,186 as compared with 999 in the preceding year. The whole question of nutrition is receiving the attention of Government and a Central Nutrition Committee has been formed (see also this *Bulletin* 1938 Supp. p. 43*).

Helminthic Diseases—During the year 5,889 cases of *ascariasis* 395 of *ankylostomiasis* 274 of *trichuriasis* and 72 of *schistosomiasis* were dealt with. At the Laboratory where 1,848 faecal specimens were examined 489 contained *ankylostome* ova, 417 *Ascaris* 139 *Trichuris* and only 1 *S. mansoni*.

Venereal Diseases.—A decrease in the number of cases of syphilis and an increase in gonorrhoea cases is reported. 3 174 cases of the latter and 566 cases of the former were recorded. At the Venereal Diseases Clinic, Freetown, 680 cases were dealt with gonococcal infections accounting for approximately 70 per cent of the total. During the year 9 312 cases of sores were treated. A special survey is in progress with a view to ascertaining whether a mass attack by means of arsenicals should be instituted in the Protectorate.

Other diseases referred to in the Report under review include the following. Of *leprosy* 126 cases with 1 death were reported. No cases of *antrax* among Europeans were recorded, but there were 49 African cases with 10 deaths. Although a slight decrease in the number of cases of *chronic rheumatism* is recorded 9 497 cases were treated during the year. Five non-fatal cases of *trypanosomiasis* were reported.

In addition to the *Laboratory Report* (see below) a number of detailed *Special Reports* are presented in the Annual Medical Report. These include (a) the Report of the *Kissy Lunatic Asylum* (b) *Freetown Prison* (c) Report of the *Surgical Specialist*, Connaught Hospital (d) *Maternity and Child Welfare Work* (e) *Eye Clinic* and (f) Report of the *I. D. Clinic*.

Scientific.—The Report of the Pathologist incorporates all work performed in the Connaught Hospital Laboratory and also those examinations carried out by the Sir Alfred Jones Research Laboratory (see this *Bulletin* 1938 Supp. p. 42* and 44*). The principal specimens examined and findings recorded have been the subject of brief reference in various sections of this summary.

Financial.—Total expenditure on Medical and Sanitary Services during 1937 amounted to £72,783 of which £52,121 represented Medical and £20 662 Sanitary expenditure.

COLONY OF THE GAMBIA (1937)

The Colony of the Gambia was created in 1843 previously from 1807 having been under the Government of Sierra Leone, and was constituted a separate government 45 years later in 1888. It now consists of the island of St. Mary (on which is Bathurst, the seat of Government), British Kumbo, Alfreeda, the Ceded Mile, the territories of Brefet and Bajana and MacCarthy Island. This last forms the line of demarcation between the Upper and Lower portions of the Gambia River. The total area of the Colony and Protectorate is 4 132 sq. miles.

Vital Statistics.—Attention continues to be drawn to the fact that the estimated population is a doubtful figure and must remain erroneous until the next general census is carried out. The available vital statistical facts relate to Bathurst and read as follows.—

Item	Africans	Europeans and Whites
Estimated population	14 097	232
Births recorded	370	—
Birth Rate	26.2	—
Deaths recorded	414	6
Death Rate	29.3	—
Infant Mortality Rate (per 1 000 live births)	254.1	—
Stillbirth Rate (per 1 000 live births)	113.5	—

The *General European population* (exclusive of Government Officials) was estimated to number 163 within this group the six deaths occurred

European Officials resident numbered 69 with an average number resident of 62. Fifty-one officials were on the sick list during the year subtertian malaria and influenza being responsible for 28 cases three invalidings were recorded. *African Officials resident* numbered 391 with an average number resident of 341. Within this group 415 were on the sick list at some time during the year 6 were invalided and 5 deaths were recorded

Maternity and Child Welfare Work—The results of the year's work carried out in the clinics at Bathurst are said to have been most encouraging numbers increased African women developed a wider interest in the work and many of them continued to attend the clinics regularly after the birth of their babies. In the Clinic Ward of the Victoria Hospital 84 confinements were conducted and there were 44 ante-natal patients. In the Out patient Department 260 women attended the ante natal clinics totalling 1,313 attendances and there were 363 babies on the registers of the Baby Clinics. Of the 370 births recorded in Bathurst 141 were conducted under the supervision of the Clinics

At the Sukutu Clinic good work continued to be done 234 patients recorded 2 304 attendances at the General Clinic and 15 ante-natal patients made 53 attendances. New buildings are to be erected. Ante natal work has also been started at Bwiam by the Medical Officer and satisfactory progress is reported

School Hygiene—The only references to this important branch of work appear in the Report of the Dental Surgeon who states work at the Clinic is primarily devoted to children that there has been a steady growth in the interest and appreciation of dental work in the schools and that the increased record of work was mainly due to the satisfactory attendances of the school-children for treatment. During the year 1 632 school-children were dealt with

Public Health Sanitation etc—Methods of sewage disposal remain for all practical purposes as previously described (see this *Bulletin* 1938 Supp. p. 46*) No system of water-borne sewage can be considered until the Reclamation Scheme in Bathurst is completed and proper drainage of the town provided no effective method has yet been devised for dealing with crabholes (see this *Bulletin* 1938 Supp. p. 45*) which continue to be responsible for excessive mosquito breeding. The system of refuse disposal is said to function satisfactorily even though a number of people still consider the compound as the

most suitable depository for household refuse. Sanitation in the Protectorate is still in its infancy though gradual improvement is being effected through the efforts of the Inspectors stationed in various towns. In one town a night soil service has been provided, and in several towns public latrines have been erected. The bush type septic tanks mentioned in the 1936 Report are reported to be functioning satisfactorily (see this *Bulletin* 1938 Supp. p. 46*).

The supply of water in Bathurst is reported to be adequate as regards quantity and of satisfactory quality. The old water mains are gradually being replaced throughout the town. *Housing and Town Planning* matters continue to receive attention, and a Technical Assistant was appointed to the Public Works Department to supervise and inspect new plans and buildings. Septic tanks and water are installed in four new houses erected, but it is stated that the rigid enforcement of the laws relating to buildings and the solution of the housing problem are dependent upon completion of the Reclamation Scheme. *Markets and Foods* exposed for sale are regularly supervised. Regulations have been made to ensure that hawkers maintain a prescribed standard of cleanliness in so far as their wares are concerned.

The usual measures were taken to spread the knowledge of hygiene and sanitation among school-children and the population at large. Courses of lectures on sanitary law and matters of sanitation were held and attended by the sanitary personnel.

Port Health Work—During the year 279 ships were boarded and inspected and where necessary deck passengers were kept under surveillance. Rat-catching was continued, rats found dead were examined for *P. pestis* but all gave negative findings. The Protectorate of the Gambia was declared an infected local area owing to smallpox in April and quarantine regulations were applied during the year to Gold Coast Colony and to places in Senegal on account of yellow fever. All the 135 aeroplanes and seaplanes arriving during the year had clean bills of health.

Hospitals, Dispensaries, etc.—A new Protectorate Hospital is under construction at Bansaung. This institution is to be admirably equipped and when completed will replace the present Georgetown Hospital. A Leper Camp was opened during the year at Bwiam and has grown much more rapidly than was anticipated.

The four *Dispensaries* continue to do good work in their respective areas (see this *Bulletin* 1938, Supp. p. 47*). Some difficulty is experienced in exercising adequate supervision of these centres by Medical Officers and steps are being taken to devise a means of dealing with their more efficient control. The records of work dealt with at Hospitals and Dispensaries during the year under review may be set out as shown in table overleaf p. 41*.

The notes which follow briefly summarize the principal references in the 1937 Report to mortality experience in the Gambia during the year under review.

Cases of malaria treated during the year numbered 1 029 distributed as to 13 benign tertian, 763 subtertian, 1 malarial cachexia and 252 unclassified. Of the total cases dealt with 667 were treated at the Victoria Hospital, Bathurst, 86 of them as in-patients, 77 at Georgetown Hospital, of which 6 only were in-patients and 285 out-patients at Bwiam Hospital. No case of *blackwater fever* was recorded in the

Hospitals during the year but a fatal European case was reported from the town of Jawarra North Bank Province (see below under *Scientific*)

Centro	In patients			Out patients
	Admitted	Treated	Deaths	
Victoria Hospital Bathurst	1 060	1 133	131	19 475
Prison Hospital Bathurst	—	89	—	131
Georgetown Hospital	412	462	69	5 896
Bwiam Hospital	108	115	12	6 291
Basse Dispensary	—	—	—	8 642
Kanur Dispensary	—	—	—	7 076
Kaiaf Dispensary	—	—	—	3,235
Herewan Dispensary	—	—	—	6,214

The usual routine anti malarial measures continued to be regularly carried out in Bathurst regular and persistent house-to-house inspections were maintained and the prophylactic use of quinine advised and encouraged. It is pointed out that no sanitary efforts can hope to eradicate mosquito-borne diseases until proper drainage under the completed Reclamation Scheme has been provided.

No case of *yellow fever* was recorded the immunization of Europeans was rigorously insisted upon after the 1934 epidemic but more recently many persons neglected this wise precaution. Towards the end of 1937 an intensive campaign was instituted with the result that practically all Europeans and not a few Syrians have now been inoculated. The larval index for Bathurst for the year was 0.22 but in outstations the figure ranges between 0.13 in Basse to 5.20 in Barra. An outbreak of *smallpox* involving practically the whole of the Protectorate occurred from March to June. Nine cases with 1 death are mentioned but it is stated that dependable figures of cases and deaths are lacking owing to the widespread nature of the epidemic. The usual measures of isolation segregation and vaccination were carried out in Bathurst 12 903 and in the Protectorate 14 775 vaccinations were performed. No case of *plague* was reported (see above *Port Health*).

Trypanosomiasis is reported to be still increasing and is said to be still the great danger of the Colony. During the year 2 025 cases were dealt with at the three hospitals with 37 deaths and 37 were treated at Government Dispensaries. A survey of the population was carried out in MacCarthy Island and North Bank Provinces between March and June 1937 by Dr J. L. LOCHHEAD and during the course of the investigations 7 151 persons were examined. In an Appendix to the Report under review this enquiry and the results recorded are presented in detail but for present purposes a brief summary of the principal findings must suffice. Dr Lochhead found the disease present in all the areas he visited with incidence ranging from 1 to about 12 per cent between village and village though he believes his figures under-estimate the actual incidence of the disease. His recommendations include bush clearance around villages removal

regular tours of inspection of all bush villages. If financial provision can be made it is hoped to inaugurate an anti-trypanosomiasis campaign in 1939.

Only 1 (non fatal) case of *enteric fever* appears in the Hospital Returns but of *dysentery* 123 cases with 4 deaths are recorded, and of the totals 63 were amoebic (and responsible for the 4 deaths) 38 bacillary and 22 were unclassified as to type of infection.

Tuberculosis (all forms) was responsible for 231 cases with 16 deaths 211 of the cases and 14 of the deaths were ascribed to the *pulmonary* form of the disease. No facilities exist at present for the isolation of cases. sputum-positive cases are treated in the medical wards of the hospitals and in case of death the house and clothing of the deceased person are disinfected. Hospital Returns also show that 4 167 persons suffering from *bronchitis* and *broncho-pneumonia* were treated as in- and out patients with 13 deaths and 97 *pneumonia* cases were dealt with and 20 deaths ascribed to this cause.

Helminthic diseases are widely prevalent and directly due to bad sanitation and pollution of ground and water. The recorded figures of cases treated though no indication of the actual incidence of these diseases read *ascariasis* 1 449 *ankylostomiasis* 91 *schistosomiasis* 74 and *taeniasis* 128 (see this *Bulletin* 1938 Supp. p. 48*).

Leprosy—Mention has already been made of the establishment of a new leper camp at Bwiam (see *Hospitals* above). The Leper Colony at Buruko MacCarthy Island Province has functioned with steadily increasing success (see this *Bulletin* 1938 Supp. p. 48*) it has been suggested that a village be erected in the vicinity for the accommodation of relatives of the Leper Colony. In the whole territory 399 cases of leprosy were recorded. At the two Leper Colonies in the Protectorate 113 advanced cases were admitted during the year 4 deaths were recorded 60 patients were discharged and at the end of the year there were 73 patients still under treatment. During the course of his sleeping sickness survey (see above) Dr. Lochhead reports that very few persons were seen suffering from the disease.

Veneral diseases do not appear to be mentioned in the text of the Report but Hospital Returns show that 129 persons were treated for *syphilis* 568 for gonococcal infections, and 23 for soft chancre. There were 1 642 cases of *syphilis* the majority of these occurring in the Protectorate. Attention is called to the fact that while in 1936 Georgetown returned 1,948 cases of the disease (see this *Bulletin* 1938 Supp. p. 49*) from the same area only 1 171 cases were recorded during 1937. It is thought that the decrease may be due to the fact that cases were not recorded as *syphilis* without obvious clinical signs, or that treatment and improved sanitary conditions have contributed to an actual decline in the incidence of the disease. In his report of the sleeping sickness survey Dr. Lochhead speaks of the disease being met with everywhere and says that probably 20 per cent. of the people show some signs of having had the disease.

Other diseases referred to in the Report under review include 1 024 cases of *influenza* mainly resulting from a sharp outbreak of the disease in Bathurst in July 188 cases of *filarial elephantiasis* 23 of *whooping cough* and 3 of *measles*. It is stated that during the year 19 deaths were ascribed to *tetanus*. Hospital Returns show 15 cases with 7 deaths.

Scientific—The Report of the Victoria Hospital Laboratory Bathurst records the numbers of specimens received and examined during the year but findings are not recorded. Dr MURCATROYD of the Liverpool School of Tropical Medicine continued his investigations in the chemotherapy of trypanosomiasis but had to return to England before this work was completed (see this *Bulletin* 1938 Vol. 35 p. 340 and Supp. p. 49*) In an Appendix to the Report are given the results of the pathological findings of a suspected case of blackwater fever (see above *malaria*) which occurred at Jawarra and terminated fatally. Owing to marked *post mortem* changes in the specimen examined conclusive diagnosis proved difficult.

Financial—Total expenditure during 1937 on the Medical and Health Services amounted to £32 109 a sum which represents 9.3 per cent. of the total expenditure of the Colony.

EAST AFRICA

KENYA COLONY AND PROTECTORATE (1937)

Kenya Colony and Protectorate is in Eastern Equatorial Africa. It is bounded on the north by Abyssinia and the Sudan, on the west by Uganda, on the south by Tanganyika Territory and on the east by the Indian Ocean and Italian Somaliland. The total area is 224 960 sq miles and is divided into nine provinces: Nyanza, North Turkana, Rift Valley, Masai, Kikuyu, Ukamba, the Coast, and the Northern Frontier Provinces. Its capital is Nairobi and Mombasa the principal port.

Vital Statistics—For several years each Annual Medical Report has called attention to the fact that no system of vital registration is established in the Colony and Protectorate of Kenya. The Report under review observes that this important requirement still remains unfulfilled and that deductions which, with the assistance of dependable vital statistics might be drawn with reasonable accuracy as regards the state of the public health, must give way to a more speculative assessment based upon such information as becomes available from institutional and district reports (see this Bulletin 1933 Supp. p. 33*, 1937 Supp. p. 39* and 1938 Supp. p. 50*). It is of the utmost importance that an effective system of vital registration should be established if health administration is to progress along organized and economic lines. Birth, death and infant mortality rates cannot be calculated: the only data available are the following—

Race	Estimated Population	Births	Deaths	Immigrants	Emigrants
Europeans and Whites	19 311	313	119	6 258	5 668
Africans	3,253,689	65	1 710	2,743	1,966
Arabs and Others	15 285				
Asiatics, Indians, Goans	42 368				
	3 658	98	33	793	687

European Officials resident numbered 1,865 with an average number resident of 1,430. Six died and four were invalided. *Non-European Officials* resident numbered 2,433 with an average number resident of 2,090. Seven died and seven were invalided.

Maternity and Child Welfare Work—It is said that in no other branch of the Department's activities has there been greater comparative progress than in this. A few years ago great difficulty was experienced in persuading women to attend treatment centres for ante-natal and maternal care whereas nowadays the difficulty is to provide accommodation for them. The actual work is undertaken by Government and Local Authorities both European and African Missions, and the Lady Grigg Welfare League. *The training of Asian and African Midwives* continues at Nairobi with the object of providing increased maternity facilities for these sections of the community during the year under review 17 African midwives were in training

and 3 qualified and at the Indian centre where 4 were in training 1 qualified.

The Missionary Societies Municipal Council of Nairobi, and the Lady Grigg Welfare League continue to receive financial assistance from Government for the work they undertake. Figures for maternity work carried out during the year read as follows —

	Maternity cases
At 9 Government Hospitals	359
At 7 Centres established with the help of Local Native Council Funds	1 313
At 3 Centres of the Lady Grigg Welfare League	629
At 8 Missionary Society Centres	1 071*

[*In another section of the Report given as 971]

Ante Natal and Child Welfare Work is undertaken by the Medical Department at 5 centres in Mombasa and 1 in Eldoret and by the Municipal Council in Nairobi. The volume of work dealt with is summarized below —

	Attendances.	Home Visits.
Mombasa	40 240	19 721
Eldoret	4 831	4,975
Nairobi	60,999	15,812

School Hygiene—Once again it is reported. No school medical service exists at the moment. In townships and native reserves medical officers and sanitary inspectors have devoted much attention towards improving the general hygienic conditions of schools and their endeavours have met with success. The health and dietaries of school-children are said to be supervised so far as circumstances will allow.

Public Health Sanitation etc—Though no appreciable extension of medical services was possible considerable progress is recorded during the year no serious outbreak of infectious disease occurred the general health of the people is said to have been on the whole satisfactory (see comments on assessments of the state of the public health *Vital Statistics* above). The part played by local bodies as Public Health Authorities increases and their duties have in general been efficiently discharged. Public health activities in the *Native Reserves* were maintained the Local Native Councils are proving important and progressive influences in their respective areas. The general scheme of work as applied to the native reserves is said to have exceeded all expectations—the experimental stage is giving way to a settled and progressive policy and particularly good results are reported with regard to *housing* and the cleaner village campaigns.

A notable event in the year's Public Health history was the sudden incursion of some 7 000 Abyssinian refugees in June and July introducing medical problems of no little magnitude, which however were successfully dealt with. The incursion is described in detail in the Report under review.

Routine and *anti-malarial measures* were continued throughout the year and experiments with various larvicides were carried out. Marked progress is reported in connexion with the anti-malarial scheme at Kisumu (see this *Bulletin* 1933, Supp. p 51*)

A marked improvement is reported in the *general sanitation* of the smaller townships and trading centres a number of them are now provided with *water supplies* and *night soil* and *refuse disposal* services are being extended. Sanitary conditions in the larger towns continue to improve and are said to be fairly satisfactory.

While no major schemes of *housing and town planning* were undertaken the campaign directed towards development and progress in these matters continued and increased provision of housing in permanent material is reported. The *nutritional state* of the population shows some evidence of improvement with decline in the grosser manifestations of *hypovitaminosis* it is added that the nutritional problem should be investigated very fully. The usual inspection and control of foods and drinks was continued.

The position with regard to recruitment housing, etc. of African labourers cannot be described as altogether satisfactory. On the other hand many employers are effecting improvements as circumstances permit.

The systematic *training of African sanitary personnel* has not yet been placed on an organized basis. Suitable African candidates engaged for work in the native reserves have been trained as sanitary assistants under a European Sanitary Inspector.

Port Health Work—During the year 738 steamships and 1427 dhows entered Kikindini or Mombasa harbours, 19423 passengers were medically inspected and 269 passengers landed under surveillance. No ship arrived with any case of major infection among passengers or crew. Rat destruction work continued to be carried out. 11411 rats were trapped and 833 were examined for plague none being found infected. (In the Laboratory Report mention is made of the examination of 30 rats, 15 of them proving positive with *P. pestis*.)

With regard to *aerial traffic* the position in respect to authorized landing grounds remains as previously described (see this *Bulletin* 1938 Supp p 52). Mosquito surveys were carried out at airports during the year and the numbers of houses and trees with *Aedes aegypti* recorded. the *Aedes* index was found to range from 0.01 per cent in Kisumu to 18 per cent in Nairobi.

Hospitals Dispensaries etc—The growing number of Africans who seek admission to hospitals is throwing an increasing strain on available accommodation. most hospitals are overcrowded to a degree which causes anxiety. In the native reserves no new hospitals were opened but some additional accommodation was provided at existing institutions from funds made available almost entirely by Local Native Councils. Progress in connexion with preparation of the plans for the new Group Hospital in Nairobi is recorded, and it is expected that building operations will be commenced in 1938.

The fact that in 1937 over 130000 more persons received medical treatment than in the preceding year is not necessarily indicative of increased invalidity but more probably of greater appreciation of medical facilities and faith in European treatment. The volume of work dealt with at all treatment centres may be summarized as follows:—

	In-patients	Deaths	Out patients.
Europeans	1788	29	2765
Asiatics and Africans	50,915	2,706	468,469

A further analysis of the above figures shows that of the gross totals 27,907 in patients were treated at institutions in Townships 943 in Turkana Northern Frontier Province and Lamu and 23,853 in hospitals in native reserves the figures for out patients being given as 209,559 42,864 and 239,958 respectively. [Gross totals for out patients are not in agreement viz for Europeans Asiatics and Africans in the first statement read 469,234 and in the second 492,681.]

In addition at *Out Dispensaries* 645,688 persons received medical treatment during the year.

To *Prison Hospitals* 2,988 patients were admitted and 83 died and to the *Muthari Mental Hospital* 153 cases were admitted 254 were treated and 14 died. [These figures are presumably included in the gross totals quoted above.]

At 8 *Mission Hospitals* 9,054 in patients and 151,254 out patients were dealt with. Figures for Out Dispensary treatments are given for four hospitals only.

The training of Africans to qualify as hospital assistants or nursing orderlies was continued. Eleven candidates qualified as hospital assistants and of three compounders under training two passed the final examination. It has not been possible to arrange for the systematic training of African women as nurses but facilities will be provided on completion of the new Group Hospital at Nairobi.

The notes which follow briefly summarize the references to the more outstanding causes of morbidity and mortality based upon information obtainable from institutional and district reports for the year under review.

Malaria was the principal cause of morbidity and is said to have been responsible for 43,850 cases (exclusive of cases treated at Out Dispensaries) with 209 deaths (see below). An epidemic wave of the disease affected practically the whole Colony during and after the long rains which were exceptionally heavy, the only areas not recording heavy incidence being the Fort Hall and Meru districts of the Central Province and Teita district in the Coast Province. The town of Mombasa experienced the worst visitation for some years and in Nairobi the number of cases was higher than in 1936. According to Hospital Returns the cases of malaria treated for Europeans and Non Europeans classified by types of infection for in and out patients read as follows —

Type	Europeans			Asiatics and Africans			Total cases all classes
	In patients	Deaths	Out patients	In patients	Deaths	Out patients	
Subtertian	140	2	127	3,925	107	7,408	11,600
Benign Tertian	66	—	6	489	15	1,315	1,875
Quartan	2	—	6	178	7	588	784
Clinical	55	—	119	1,804	29	22,282	24,260
Cachexia	—	—	—	31	8	283	319
Cerebral	1	—	—	40	28	—	47
Undifferentiated	45	—	13	402	5	4,366	4,826
Totals	309	2	270	6,869	199	36,257	43,705

It will be seen that 43 705 cases were dealt with (not 43 650 stated in the first place) with 201 deaths and that 579 of the cases and 2 deaths occurred among Europeans. In addition there were 26 cases of *blackwater fever* with 8 deaths 7 of the cases and 1 death occurring among Europeans.

At the Medical Research Laboratory where 16 087 blood films were examined 2 285 were positive with *P. falciparum* 118 *P. vivax* 49 *P. malariae* 1 *P. ovale* 79 *P. falciparum* (crescents) and 40 were mixed infections. At the Clinical Laboratory Mombasa among 6 951 blood films examined 1 300 contained *P. falciparum* 47 *P. malariae* and 15 *P. vivax*.

Yellow fever is still unrecorded in the Colony and so far no mouse-protection test has been positive. A small *Aedes* survey was carried out by the Section of Medical Entomology in a rural area of Central Kavirondo and an *Aedes aegypti* breeding index of 0.4 was recorded. Kisumu township is said to have been free from *Aedes aegypti* for some years. Control measures are to be extended to other areas.

Smallpox imported by Abyssinian refugees (see above *Public Health*) was confined by energetic action to the Northern Frontier District where "two to three hundred cases occurred. Routine vaccination was continued and 13 013 vaccinations performed.

Plague 158 cases reported (68 recorded in Hospital Returns with 41 deaths) 12 of these occurring in the European farming district of Nakuru 11 from one farm alone and 25 within the Nairobi Municipal area. The clearing and cleansing campaign commenced in the Central Province was continued with extension to all other areas (see also *Port Health* (Fork above)).

It is said that 24 cases of typhus were recorded with the additional comment that many cases occurred among Abyssinian refugees. Hospital Returns show only 8 in-patient cases and 1 death 7 of the cases (all non-fatal) occurred among Europeans. A decline in the incidence of *cerebrospinal meningitis* is recorded, cases numbering 227 of these 216 were treated as in-patients (1 European only) with 134 deaths. Abyssinian refugees are also said to have imported *relapsing fever*. Classified returns show 63 cases with 1 death among 10 in-patients. Twelve cases of *undulant fever* were notified the serum of all cases agglutinated positively with *Br. abortus*. Other infections included 124 reported cases of *anthrax* (79 in-patients 5 deaths all non-Europeans) and 23 African cases of *diphtheria* with 3 deaths.

Fatieric fever was responsible for 243 cases and 54 deaths. At the Medical Research Laboratory among 784 specimens of serum tested for agglutinins against the enterica group 175 reacted positively with *Bact. typhosum* 5 with *Bact. paratyphosum A* and 11 with *Bact. paratyphosum B*. In one section of the Report it is stated that cases of dysentery numbered 3 404 but the classified Hospital Returns record 3 438 the distribution of types of infection being amoebic 1 663 bacillary 172 and undefined 1 601. The importance of amoebiasis as a cause of invalidity is emphasized in several District Reports though conflicting reports are made as regards the saprophytic existence of *E. histolytica*. At the Medical Research Laboratory *E. histolytica* was found in 457 cases among 9 823 faecal specimens examined and at the Mombasa Clinical Laboratory 298 times among 4 503 specimens.

Thirty cases of *trypanosomiasis* are said to have been treated as in patients [27 in Hospital Returns plus 3 out patients] and in addition 103 cases were noted among outstation dispensary patients and during visits to special areas. Incidence seems to be confined to the Central and South Kavirondo districts along the Lake shore. During the year 9 740 natives were examined 762 gland and blood examinations made and 21 new cases discovered. Control measures by the block and barrier method were continued and the question of the settlement of natives on reclaimed areas under controlled conditions was considered.

In the text of the Report it is stated that 1,391 cases of *tuberculosis* were treated but the classified Hospital Returns show 1 451 cases of all forms of the disease and of this total 895 were *pulmonary* cases. 8 of the *pulmonary* cases were Europeans one died, and 560 were Africans and Asiatics and of these 153 died. Recorded cases are said to be no true index of incidence among the general population. An extension of facilities for sanatorium treatment is said to be urgently required. At the Medical Research Laboratory 122 out of 1 394 specimens of sputum were positive with *Mycobacterium tuberculosis* and at the Mombasa Clinical Laboratory 149 positives were recorded among 600 specimens examined. *Pneumonia* (all forms) kills more than *tuberculosis*—807 deaths were ascribed to *pneumonia* as against 154 for *tuberculosis*. Cases of *pneumonia* treated numbered 4 133 and of these 3 025 were in patients. 20 were Europeans and 4 died. Prominent among other *respiratory affections* were *bronchitis* with 50,364 cases and 26 deaths and *asthma* with 1 148 cases and 5 deaths.

Helminthic diseases—The following data extracted from Hospital Returns relate to the principal infections dealt with. (They are not in agreement with the figures quoted on p. 18 of the Report under review) —

Infection	In-patients		Out patients		Totals All Races
	Europeans	Others	Europeans	Others	
Ankylostomiasis	5	872	1	1 485	2,363
Ascariasis	2	663	2	8 630	9 297
Taeniasis	5	951	2	46,558	47 516
Dracontiasis	—	4	—	6	10
Schistosomiasis	5	353	2	525	895

At the Medical Research Laboratory where 9,823 faecal specimens were examined, the ova of *Taenia* were found in 1,836 of *Ascaris* in 1,241 of *ankylostome* in 1 123 and *S. mansoni* 166 and at the Mombasa Clinical Laboratory the following *helminths* were found during examination of 4 603 faecal specimens—*ankylostome* 1,213 *Ascaris* 787 *Taenia* 474 *Trichuris* 929 and *S. mansoni* 111.

Leper patients are cared for at the Government Camps maintained at Kakamega and Mombasa, and in addition 55 beds are reserved for cases at certain Mission Hospitals. During the year 179 cases were under treatment at Kakamega and 63 at Mombasa—these numbers

are no true assessment of the incidence of leprosy which is believed to be increasing. A tentative scheme for the control of the disease in the Kavirondo Reserve has been well received by a Committee of the Local Native Council—good results are anticipated when this scheme becomes fully effective.

Clinics for the treatment of venereal disease remain as previously described (see this *Bulletin* 1936 Supp. p. 55*). Total cases treated during the year were, syphilis 8,954 soft chancres 157 gonococcal infections 4,141 and granuloma venereum 2. The only European cases were 4 for syphilis and 5 for gonococcal infections. At the Medical Research Laboratory the Kahn test was applied to 4,014 specimens of sera—1,585 gave positive and 328 doubtful reactions. Among 289 urethral smears 102 were positive with *N. gonorrhoeae* and 13 out of 64 cervical and vaginal smears were positive. At the Mombasa Clinical Laboratory where 660 specimens of urethral exudate were examined 297 gave positive results.

For yaws 13,174 persons received treatment according to the classified Hospital Returns. The general impression seems to be that yaws is decreasing in most areas.

Other diseases mentioned in the Report and calling for brief mention in this Summary, include the following—

Diseases of the Eye are under the control of the Ophthalmic Specialist appointed during the year. Two wards for the admission of cases have been provided at the Nairobi General Hospital and clinics are held daily at the General Dispensary. According to Hospital Returns 18,635 cases were dealt with and of these 225 were cases of trachoma—it is said the recorded cases of trachoma understate the actual incidence of the disease. *Malignant diseases* were responsible for 167 cases, *acute rheumatism* for 3,947 cases, *ulcers* for 36,435 cases and *external causes* 65,548 cases.

Scientific—Dr F. W. LESTER contributes his usual detailed account of the activities of the Medical Research Laboratory and records a further increase in the volume of work dealt with in 1937. The results of the routine examination of a total of 58,829 specimens are tabulated—some of these are discussed under various headings in the preceding notes. The increases in routine diagnostic work and the preparation of laboratory products occupy the full time of the staff to the detriment of research work, yet among important investigations undertaken the following may be mentioned. In the Prison Hospital, Nairobi, a helminthic investigation is in progress having special reference to the efficacy of various drugs on intestinal helminths. A survey of *Bac. typhosum* "H" and "O" agglutinins in sera from Africans not suspected of suffering from typhoid was completed and the results published under the title "*Typhoid Agglutinins in the Native Population*" by R. M. DOWDSEWILL, *Trans. Roy. Soc. Trop. Med.* Vol. 31, Nov. 1937. An examination of the dietaries in use in Government Native Hospitals was made and a large-scale rat feeding experiment was planned and is in progress.

A résumé of the year's work at the Mombasa Clinical Laboratory appears in an Appendix.

The Report of the Section of Medical Entomology describes the mosquito surveys and malaria control work carried out, the searches for insects in aeroplanes landing in the Colony, work concerned with

the elimination of *tsetse flies* and sleeping sickness control fly breeding and a rat flea survey The following paper was published —

EVANS (A M) & SYMES (C B) *Anopheles funestus* and its allies in Kenya
Ann Trop Med & Parasit 1937 Apr Vol 31

Financial —Actual expenditure during 1937 on Medical Department services amounted to £213 758 as compared with a sanctioned estimate of £210 448 Expenditure represents 6.1 per cent. of the total estimated expenditure for the Colony and Protectorate during the year under review

UGANDA PROTECTORATE (1937)

The Uganda Protectorate lies in the northern part of the Great Lakes region of Africa It has no sea coast, being bounded by the Anglo-Egyptian Sudan on the north Kenya Colony on the east, Lake Victoria Nyanza and the Tanganyika Territory on the south, and the Belgian Colony on the west The area of the Protectorate is estimated at 94 204 sq miles, including 13 616 sq miles of water (The area of England without Wales is a little over 50 000 sq miles) The head quarters are at Entebbe and the chief commercial towns are Kampala and Jinja. All three are on or near the north shore of Lake Victoria

Total Statistics —For the native population only the principal facts are as follows —

Province	Estimated Population	Live Births	Birth Rate	Deaths	Death Rate	Infant Deaths	I.S.L.R.
Buganda	888,244	20 073	22.6	16,004	18.0	1,593	79.4
Eastern	1 189,204	29 977	25.2	26,141	22.0	5 183	173.1
Western	741,281	19 010	25.6	11,921	16.1	2,494	131.2
Northern	807,820	23 009	28.5	14 669	18.2	5 057	219.8
Protectorate	3 628,549	92,069	25.4	68 735	18.9	14,332	155.7

The above figures summarize the excellent Tables which provide data in great detail for both Provinces and Districts in the Protectorate.

European Officials resident numbered 595 with an average number resident of 499 One invaliding and four deaths were recorded. Among European non-officials 1,837 cases of sickness were treated by Government Medical Officers *malaria* accounting for 371 of the cases dealt with *injuries* 113 and *diseases of the digestive system* 110 there were 16 deaths recorded among European non-officials.

Asian Officials resident numbered 337 with an average number resident of 323 three were invalided but no deaths were recorded The Government Medical staff treated 8 124 cases of sickness among Asian non-officials and 75 deaths were reported within this group.

African Officials (African Civil Service) resident numbered 212 with an average number resident of also 212 There were no invalidings, but one death occurred within this group

Among all groups of officials and non-officials *malaria* was the principal cause of ill health

Maternity and Child Welfare—Though the Provincial and District infant mortality and maternal mortality rates have been subject to variation during the past seven years, for the Protectorate as a whole these rates have declined steadily and testify to the efficacy of ante-natal and child welfare work in the territory. It is said that little progress has been made in increasing the number of maternity centres, yet despite this and other handicaps the tabulated facts supply ample evidence not only of the considerable volume of work dealt with but also of the success achieved in this important field. For example during the year under review 16,678 women attended for ante-natal supervision at the larger centres, 1,745 of them terminated their pregnancies in hospitals or at maternity centres and among them 1,578 live births and 62 maternal deaths were recorded. On the other hand a further 484 women who had not availed themselves of ante-natal treatment were delivered in hospitals of 311 live babies with 42 maternal deaths. The figures for those who did not attend for ante-natal supervision again compare unfavourably with those who did. Then again, 2,116 women after attending ante-natal centres were reported to have been confined in their own homes where they gave birth to 2,024 live babies with only 18 maternal deaths. *Infants attending Welfare Centres* numbered 17,792—these figures relate only to healthy children brought to the centres for advice and supervision—sick children are included in hospital and dispensary returns.

Patients admitted to the wards of the *Lady Coryndon Maternity School* numbered 569 during the year 410 confinements, 312 live births 14 infant deaths and 33 maternal deaths were recorded. The Out-patient Department dealt with 2,948 expectant mothers and undertook the post-natal supervision of 651 babies. At 22 country centres there were 1,809 confinements, 1,523 live babies were born infant deaths numbered 37 and maternal deaths 6 at these centres 11,184 new ante-natal cases were dealt with, 13,860 attendances were recorded at child welfare clinics and total out-patient attendances were 68,742.

To the wards of the *Nsambya Maternity Training School* 371 patients were admitted, confinements numbered 295 live births 260 while 18 infant deaths and 10 maternal deaths were recorded. At 15 country centres confinements totalled 1,806, live births 1,805 infant deaths 23 and maternal deaths 11 records at these centres also include mention of 4,272 new ante-natal cases 2,892 attendances at child welfare clinics, and 37,872 out-patient attendances.

With regard to the *training of nurses and midwives* at the *Lady Coryndon Maternity Training School*, of the 39 students in training, 14 were successful in obtaining the Certificate of the Uganda Midwives Board, and at the *Nsambya Maternity Training School*, 7 of the 30 native students in training obtained this qualification. There are now 63 European and Asian and 217 African Midwives on the registers of the Uganda Midwives Board. It remains to add that during the year a district midwife was posted to the township of Hobna for special ante-natal work among native women. If this experiment proves successful it may lead to extension of trained supervision of maternity work among African women with corresponding decrease in obstetrical disasters.

School Hygiene—Periodic visits of inspection continued to be made to schools in most districts by Medical Officers and their assistants (see this *Bulletin* 1938 Supp p 57*) In Busoga the Senior African Medical Assistant examined the pupils at Mwiru College treatment was provided where necessary The experiment in nutrition in the Mengo District (see this *Bulletin* 1938 Supp p 57*) was concluded with the most encouraging results In an Appendix to the Report under review Drs J Scott BROWN and L J A LOEWENTHAL report the results of the investigation under the title of *The Value of Milk as an Adjuvant to the Diet of School Boys* After a routine examination of the boys attending the C.M.S. School at Mukono 30 were chosen at random and each given half-a pint of milk on every day of attendance Briefly results show a significant extra gain in height that the small superiority in weight gain was not statistically significant and that optimum nutrition is not obtainable from normal African diets A fuller account of the investigation appeared in the *East African Medical Journal* The investigation continues and a similar experiment is in progress at Teso

Public Health Sanitation &c—No new schemes of development were introduced during the year the policy outlined in 1934 (see also this *Bulletin* 1937 Supp pp 46-47*) was however steadily pursued and of this it is said that in certain places the first fruits are beginning to appear Considerable progress is reported with the Kampala *saustrage* system and though the disposal works are not yet completed a number of houses have already been connected up to the sewers Several houses in Entebbe have septic tank installations though these cannot be brought into use until the piped water supply from Lake Victoria has been completed Government houses in Mbale also have septic tank installations operated in connexion with the newly constructed gravity water supply In Government quarters in Fort Portal the double bucket system is in use and in the larger and some of the smaller townships the single bucket system is used Dr W H KALNTZE C.M.G. Director of Medical Services contributes an interesting commentary on rural sanitation and of how sanitary ideals are to be realized in spite of inherited native beliefs The provision of a filtered and chlorinated piped water supply was partially completed in Mbale and in Entebbe while in rural areas the protection of water supplies continued to receive special attention.

With regard to *housing and town planning* it is reported that new Asian dwellings are being built to better design, that building rules are strictly enforced and that Africans are gradually developing an interest in model housing schemes The provision of cheap housing for Africans is a problem of urgency in the townships, where efforts are being made to improve living conditions by laying out plots in areas zoned for certain classes of housing A detailed description is given of a two-roomed house suited to the needs of the general African population and costing between £20-£25 to build A Committee has been appointed to investigate *labour conditions* in Uganda meanwhile the standard of housing of labourers is said to improve.

The question of *food in relation to health and disease* is receiving special attention The Report of the Nutrition Sub-Committee of the Agricultural Survey indicates that large sections of the population suffer from malnutrition steps have already been taken

with a view to improving existing conditions (see the experiments with milk diets under *School Hygiene* above). Agricultural surveys continue to be made to determine the quantity and quality of locally grown foodstuffs, while selected youths are trained in improved farm methods at farm schools at Lira and Gulu. Rules for regulating the sale of milk are in course of preparation.

Health propaganda continues to be carried out in all districts, with encouraging results.

The training of African Sanitary Inspectors has progressed satisfactorily (see this *Bulletin* 1938, Supp. p. 58*) and the final examination of the first batch of students will take place in November 1938 under the auspices of the Royal Sanitary Institute London.

Hospitals Dispensaries etc (see also this *Bulletin* 1938 Supp. p. 59). The Tororo Hospital which will provide in and out patient accommodation for Asians and Africans, approaches completion. To the Jinja Hospital, two new African wards, an Asiatic Maternity Ward out-patient block and other constructions were added. Minor improvements were carried out to other hospitals in the Protectorate. Three new dispensaries and two additional dressing posts were opened during the year.

The training of African female nurses continues at the hospitals at Namirembe and Mubaga with successful results.

The records of the year's work at hospitals and dispensaries is summarized below—

Hospitals, etc.	Beds	Admissions	Treated	Deaths	Total New Cases	Total Re-Attendances
4 European	34	533	—	—	490,234	533,727
9 Asiatic	56	1,635	—	—		
23 African	1,277	31,250	—	—		
97 Dispensaries	928	7	—	—	533,727	1,182,941
Totals	1,992	33,443	34,487	1,799	1,023,961	1,686,668

A new nomenclature has been adopted for the tabulation of diseases and deaths in the Uganda Annual Medical Reports. This new departure permits the presentation of the relevant facts within the limits of *three pages* in place of the 19 pages formerly necessary for this section.

Medical Education—The Report of the Commission appointed by the Secretary of State for the Colonies to advise on higher education in East Africa drew attention among other matters to the fact that the basic education of the African recruit to the medical course is very deficient and that his knowledge of the preliminary sciences is not of a sufficiently high standard. To meet these requirements the new biology chemistry and physics laboratory under construction at Makerere College should enable the standard of these courses to be raised considerably. A new building is to be erected to replace the present medical school which lacks adequate accommodation.

The Report of the Uganda Medical School describes the year's work and presents details of the numbers of students taking the various

grades of examination results of those examinations and the more significant comments made by the external examiners. It is noted that since 1923 thirty five students have been licensed to practise and 30 of these are in the service of the Uganda Government.

With regard to *morbidity experience* during the year it is stated that with the exception of malaria and blackwater fever a general decrease in the incidence of the major communicable and infectious diseases was noted during 1937. The notes which follow briefly summarize more extensive commentaries in the Report relating to the principal diseases dealt with at hospitals and dispensaries.

A further increase in the number of *malaria* cases is reported: 72,238 as compared with 71,407 in the preceding year (see this *Bulletin* 1938 Supp. p. 59*). Of the total cases recorded 31,314 were dealt with at station hospitals and 40,924 at dispensaries while at all centres approximately 50 per cent. of the cases were microscopically diagnosed. On the other hand the 'Return of Diseases and Deaths' shows that 32,142 in- and out-patients were treated for the disease the distribution of types of infection being *benign tertian* 1,997 *quartan* 1,304 *subtertian* 7,800 and *unclassified* 21,041 hospital deaths ascribed to the disease numbered 134. The usual routine anti-malarial measures continued to be carried out at most stations with reclamation of swampy areas sub-soil drainage controlled tipping and other works in specific areas.

Of *blackwater fever* 170 cases and 43 deaths were reported and of these 66 cases with 23 deaths were treated by Government Medical Officers and the remainder by private practitioners. Of the total cases 14 were European (4 deaths) 150 Asians (38 deaths) and only 6 African with 1 death. The incidence and distribution of blackwater fever in Uganda is set out in great detail in an admirable series of tabulated statements with distinction as to race province district age etc.

No case of *yellow fever* was reported during the year. In view of the suspicious cases reported by the District Medical Officer Masaka in 1936 that District first engaged the attention of the *Yellow Fever Commission* of the Rockefeller Foundation (see this *Bulletin* 1938 Supp. p. 60*). No cases of clinical yellow fever were seen while sera from 35 cases of fevers of undetermined origin when inoculated into animals gave negative results. Protection tests were carried out: sera from 37 children all gave negative results, but 6 from 174 adults were positive. The Commission continued investigations in the Bunyoro Chua and West Nile Districts of the Northern Province with somewhat similar results. In Bwamba County of the Toro District (Western Province) 25 sera from 53 adults gave positive findings. Protection tests were carried out on 141 people of all ages—sera from 16 were positive. Results suggest that a jungle type of yellow fever may be present in Bwamba. Measures to combat *Aedes aegypti* were continued. The Government Entomologist reports that investigations into the incidence of *Aedes aegypti* were carried out in rural areas in the West Nile District and in the vicinity of Kampala. These investigations continue.

It is said that *plague* appears to be undergoing its periodic fall in incidence and that the decrease in the number of cases during 1937 is not due to any real improvement in its control which "will only

with a view to improving existing conditions (see the experiments with milk diets under *School Hygiene* above). Agricultural surveys continue to be made to determine the quantity and quality of locally grown foodstuffs while selected youths are trained in improved farm methods at farm schools at Lira and Gulu. Rules for regulating the sale of milk are in course of preparation.

Health propaganda continues to be carried out in all districts with encouraging results.

The training of African Sanitary Inspectors has progressed satisfactorily (see this *Bulletin* 1938 Supp. p. 58*) and the final examination of the first batch of students will take place in November 1938 under the auspices of the Royal Sanitary Institute London.

Hospitals Dispensaries etc (see also this *Bulletin* 1938 Supp., p. 59*) The Tororo Hospital which will provide in and out-patient accommodation for Asians and Africans approaches completion. To the Jinja Hospital, two new African wards, an Asiatic Maternity Ward out-patient block and other constructions were added. Minor improvements were carried out to other hospitals in the Protectorate. Three new dispensaries and two additional dressing posts were opened during the year.

The training of African female nurses continues at the hospitals at Namirembe and Mulago with successful results.

The records of the year's work at hospitals and dispensaries is summarized below —

Hospitals, etc.	Beds	Admissions	Treated	Deaths	Total New Cases	Total Re-Attendances
4 European	34	538	—	—	499,834	833,727
9 Asiatic	56	1,655	—	—		
23 African	1,277	31,250	—	—		
97 Dispensaries	625	—	—	—	588,727	1,182,941
Totals	1,992	33,443	34,487	1,790	1,088,561	1,686,668

A new nomenclature has been adopted for the tabulation of diseases and deaths in the Uganda Annual Medical Reports. This new departure permits the presentation of the relevant facts within the limits of three pages in place of the 13 pages formerly necessary for this section.

Medical Education—The Report of the Commission appointed by the Secretary of State for the Colonies to advise on higher education in East Africa, drew attention among other matters to the fact that the basic education of the African recruit to the medical course is very deficient and that his knowledge of the preliminary sciences is not of a sufficiently high standard. To meet these requirements the new biology chemistry and physics laboratory under construction at Makerere College should enable the standard of these courses to be raised considerably. A new building is to be erected to replace the present medical school which lacks adequate accommodation.

The Report of the Uganda Medical School describes the year's work and presents details of the numbers of students taking the various

grades of examination results of those examinations and the more significant comments made by the external examiners. It is noted that since 1923 thirty five students have been licensed to practise and 30 of these are in the service of the Uganda Government.

With regard to *morbidity experience* during the year it is stated that with the exception of malaria and blackwater fever a general decrease in the incidence of the major communicable and infectious diseases was noted during 1937. The notes which follow briefly summarize more extensive commentaries in the Report relating to the principal diseases dealt with at hospitals and dispensaries.

A further increase in the number of *malaria* cases is reported: 72,238 as compared with 71,407 in the preceding year (see this *Bulletin* 1938 Supp. p. 59*). Of the total cases recorded 31,314 were dealt with at station hospitals and 40,924 at dispensaries, while at all centres approximately 50 per cent of the cases were microscopically diagnosed. On the other hand the 'Return of Diseases and Deaths' shows that 32,142 in- and out-patients were treated for the disease the distribution of types of infection being *benign tertian* 1,997 *quartan* 1,304 *subtertian* 7,800 and *unclassified* 21,041 hospital deaths ascribed to the disease numbered 134. The usual routine anti-malarial measures continued to be carried out at most stations with reclamation of swampy areas sub-soil drainage controlled tipping and other works in specific areas.

Of *blackwater fever* 170 cases and 43 deaths were reported, and of these 86 cases with 23 deaths were treated by Government Medical Officers and the remainder by private practitioners. Of the total cases 14 were European (4 deaths) 150 Asians (38 deaths) and only 6 African with 1 death. The incidence and distribution of blackwater fever in Uganda is set out in great detail in an admirable series of tabulated statements with distinction as to race province district age etc.

No case of *yellow fever* was reported during the year. In view of the suspicious cases reported by the District Medical Officer Masaka in 1936 that District first engaged the attention of the *Yellow Fever Commission* of the Rockefeller Foundation (see this *Bulletin* 1938 Supp. p. 60*). No cases of clinical yellow fever were seen, while sera from 35 cases of fevers of undetermined origin when inoculated into animals gave negative results. Protection tests were carried out: sera from 37 children all gave negative results but 6 from 174 adults were positive. The Commission continued investigations in the Bunyoro Chua and West Nile Districts of the Northern Province with somewhat similar results. In Bwamba County of the Toro District (Western Province) 25 sera from 53 adults gave positive findings. Protection tests were carried out on 141 people of all ages—sera from 16 were positive. Results suggest that a jungle type of yellow fever may be present in Bwamba. Measures to combat *Aedes aegypti* were continued. The Government Entomologist reports that investigations into the incidence of *Aedes aegypti* were carried out in rural areas in the West Nile District, and in the vicinity of Kampala these investigations continue.

It is said that *plague* appears to be undergoing its periodic fall in incidence and that the decrease in the number of cases during 1937 is not due to any real improvement in its control which "will only

become effective when the African builds for himself a house which contains no real harbourage for rats, and adopts habits of food storage and refuse disposal which deprive the rodent of any food. During the year under review 515 cases with 478 deaths were recorded, and of these 371 cases with 338 deaths occurred in the Eastern Province and 112 cases with 108 deaths in the Mengo District of Buganda Province. Canning of infected huts continues as a routine measure but de-batching of infected huts has been applied more extensively. At the Laboratory 377 smears were examined for the presence of *P. falciparum* but findings are not recorded. The Government Entomologist reports that tests carried out with ferrets for the detection of rats (see this *Bulletin* 1936 Sapp. p. 60*) were unsatisfactory, the size of the male animals preventing them from reaching places accessible to the rodents; two female ferrets are to be tried. Rat and flea surveys were carried out in various areas.

Of relapsing fever 453 cases were reported, but total deaths due to this cause are not stated. Of the total cases 375 were macroscopically diagnosed and 367 were treated in hospitals, with 25 deaths. The Government Entomologist experimented with various larvicides for the destruction of *O. moubata*; these tests continue. Five cases of typhus were recorded. The value of the Carnus disinfectant in controlling the disease is again emphasized (see this *Bulletin* 1936 Sapp. p. 47* and 1937 p. 49*). There were 310 cases of cerebrospinal meningitis with 118 deaths. The disease appears to be endemic in the Western Province and Masaka (Buganda Province) while sporadic cases occurred in other areas. All the cases (72) reported from Bunyaga (Eastern Province) are stated to have occurred in immigrant labourers. Segregation of contacts in temporary shelters has been continued (see this *Bulletin* 1936 Sapp. p. 61).

No case of smallpox was notified but the vaccination campaign was continued, 597,523 vaccinations were performed during the year and it is said that over 75 per cent. of the total population are now protected. Attention is being directed towards maintaining immunity by vaccinating all children at schools inspected by Medical Officers.

Trypanosomiasis.—During the year under review only 728 new cases with 14 deaths were reported. The decline in incidence by comparison with 1936 experience is striking but it is noted that the disease remains a major problem in the West Nile District where 700 of the total cases and 8 deaths occurred during 1937. The Koch River area of the West Nile District has suffered such serious depopulation through the gradual voluntary movement of the people southwards, that it is doubtful whether the small numbers of inhabitants remaining will be sufficient to maintain the clearings at the river crossings. The movement of people to new areas has served to increase the incidence of trypanosomiasis in those areas, and has introduced new difficulties and problems to be dealt with. Control measures were maintained as previously described (see this *Bulletin* 1936 Sapp. p. 61) particular attention being paid to the experimental rod-clearings which are clearings 10–20 yards wide along the banks of a stream designed to reduce fly density to limits within which the risk of infection becomes very small. The pass system allowing natives to travel between Uganda and the Sudan along certain defined routes, was introduced during the year and has

functioned successfully. Illicit movements of people have been converted into controlled movements with examination of travellers at certain gland posts. The pass system over the Tanganyika Uganda border is being maintained.

The Government Entomologist completed his tsetse fly surveys of the Gulu District. It was recommended that re-population of the restricted areas must be carried out gradually and under strict administrative control. The clearings in the West Nile and Madi areas (Northern Province) were also visited.

Cases of *tuberculosis* (all forms) among in and out patients dealt with at Government hospitals totalled 613 and of these 520 were cases of the *pulmonary* type of the disease. Hospital in-patient cases were pulmonary tuberculosis 293 with 92 deaths other forms of tuberculosis 57 with 20 deaths. The investigations of Dr CARMICHAEL, Senior Veterinary Research Officer were continued. During the year 51 specimens of sputum from phthisis patients were examined the causal organism in all cases being of the human type. It is observed that among upwards of 250 specimens of sputum examined up to the end of 1937 four were caused by the bovine type of bacillus. With regard to other respiratory ailments the *pneumoniae* were responsible for 2 038 cases and of these 1 685 were treated as hospital in-patients and 369 died. *Bronchitis* was responsible for 6 777 cases of which 439 were in patients and 6 died.

At Government hospitals 102 patients were treated for *typhoid fever* with 31 deaths, and 8 for *paratyphoid fever* with 1 death. A small epidemic which broke out in Kampala was traced to a polluted water supply. A piped water system was brought into use and the outbreak ceased within 14 days. *Dysentery* gave rise to 2 023 cases with 58 deaths the distribution of types of infection being amoebic 652 bacillary 281 and unclassified 1 090. It is also noted that the returns show 6,231 cases of *diarrhoea and enteritis* and 29 147 cases of *other diseases of the digestive system*.

Helminthic diseases especially infections with *ascaris* and *ancylostoma* are said to occur widely. Infected persons are treated with anthelmintic drugs but re-infections are frequent by reason of insanitary habits. Preventive measures are directed mainly towards the provision of latrines and educational propaganda. Of *ankylostomiasis* 1 761 cases were recorded during the year. The results of stool examinations by Medical Officers in seven areas showed infection rates ranging between 23 and 77 per cent. The condition though widespread is said to be the cause of little disability. *Taeniasis* is common in the Western Province and in districts where animal husbandry is an important industry. 2 034 cases were dealt with in Uganda during 1937. *Dracontiasis* of which 539 cases were recorded, is again said to be confined to the Nilotic districts of the Northern Province. Efforts are being made to provide protected water supplies. *Ascariasis* gave rise to 861 and *schistosomiasis* to 126 cases during the year under review. No cases of *filariasis* were treated in hospitals but *Onchocerca volvulus* is said to be extremely common in the Serubwa river area of Buganda while the infection is also said to be common round the head waters of the Nile.

Veneral Diseases show increased incidence. The incidence and distribution of *syphilis* and *gams* read as follows —

Province	Hospital Cases		Dispensary Cases	
	Syphilis	Yaws	Syphilis	Yaws
Buganda	11,961	892	19,230	2,062
Eastern	10,971	2,915	11,718	6,730
Northern	1,821	12,701	1,898	11,245
Western	2,189	4,673	8,045	22,937
Totals	26,962	32,254	40,891	43,074

The distribution of *gumma* is not given but the 16,236 cases treated are an increase over 1936 records. The results of treatment are said to be unsatisfactory owing to the irregular attendance of patients.

Leprosy.—At Government hospitals and dispensaries 1,067 lepers attended for treatment during the year under review. The Reports of the *Mission Leprosy Colonies* testify to the admirable work which continues to be carried out at these institutions. From these Reports the following details have been extracted:—

Leprosy Colony	Supervised by	Inmates
Bakula, Boga	Franciscan Sisters	89
Kyoga, Mengo		209
Banromu, Kipoti	Church Missionary Society	847
Kumi Children's Home, Tero	" "	354

Other diseases mentioned in the Official Returns include 2,403 cases of *trachoma* which still remains an important cause of blindness in Uganda. Other diseases of the eye and ear-nose were responsible for 11,725 cases. Out of 53,289 cases of affections of the skin cellular tissue and organs of locomotion no less than 35,059 were due to tropical *myiasis*. This condition was commented upon in the 1936 Report (see this Bulletin 1936 Supp. p. 63*). For rheumatic conditions 20,681 patients received treatment, nephritis gave rise to 2,927 cases and 84 deaths while 48,725 patients were treated in the group external causes.

Scientific.—The Laboratory Report records that examinations carried out during the year totalled 50,464. The numbers of specimens received and examined are grouped under various headings, parasitology serology but findings are not recorded. The Report of the Government Entomologist has already been referred to in the above summaries.

Scientific papers published by members of the staff of the Medical Department include the following:—

LOWENTHAL (L.) A. A note on Tick-typus in the Eastern Province of Uganda.—*East African Med. J.* 1936, Vol. 13, p. 141.

— The place of logic in Medical Education.—*East African Med. J.* 1936, Vol. 13, p. 204.

— Diseases of the Skin in Negroes.—*Journal of Tropical Medicine & Hygiene* from September 1936 to December 1937. A series of articles published at various times.

- LOHRENTHAL (L. J. A.) DE COURCY IRELAND (M. G.) and HOSKING (H. R.) A survey of Health and Agriculture in Teso Uganda.—Uganda Government Press, Entebbe

- Financial—Expenditure on Medical Services during 1937 amounted to £178 500 a sum which represents 9.0 per cent of the total revenue of the Protectorate during the same year

TANGANYIKA TERRITORY (1937)

Tanganyika Territory consists of that part of former German East Africa which is administered under a Mandate by His Britannic Majesty. It lies between the Great African Lakes and the Indian Ocean, and adjoins Kenya and Uganda on the north, the Belgian Congo on the west, N. Rhodesia and Nyasaland on the south west and Portuguese East Africa on the south-east. The total area is about 365 000 sq miles. Dar-es-Salaam is the capital and chief port other important towns are Tanga, Tabora, Dodoma, Moshi and Arusha.

Introductory—The Report under review was written by Dr G. MACLEAN Deputy Director (Acting Director) of Medical Services during the absence on leave from the Territory of the Director of Medical Services (Dr R. R. SCOTT M.C.)

Vital Statistics—The 1937 estimate of the native population of the Territory was 5 140,368 persons. No reliable statistics of births or infant mortality are available. (The reader is referred to the comments of the Director of Medical Services in the 1936 Report on this Bulletin 1938 Supp. p. 64*)

The non Native population is estimated to number 42 147

European Officials resident numbered 986 with an average number of 611. Twelve were invalided and four died (three of the latter in England). **Asian Officials** resident numbered 1,225 with an average number resident of 898. Eleven were invalided and one died.

Mortality and Child Welfare Work—This work was carried on at five special Clinics (13 in 1936) by Government and Missionary societies some of the latter receiving financial assistance for the work from the Native Administrations. The volume of work dealt with at these centres during the year reads as follows:—

Examinations 3,800 new cases mothers 28,813 children 49 138

Deliverances of mothers 201 136 of children 296,815

It has long been recognised that considerable advance¹ in the training of African women for maternity and child welfare work cannot be made until numbers of literate candidates become available. The Report goes on to say "Tradition which indicates matrimony as the normal goal of an African girl militates against her entry into a career wherein matrimony would be a complete hindrance or at least a paramount distraction. In these circumstances missions which influence the whole lives of their adherents are in a better position than is Government to undertake this training though results which do in fact include the provision of a certain number of midwives are stated to be disappointing on the whole compared with the efforts which are expended. The numbers of African girls attending the Government schools are rising and at 418 in 1936 were nearly three times the numbers in 1931. The Medical Department is training a few midwives at its maternity and child welfare clinics and from experience gained will be in a position to take advantage of increased literacy in due course."

It appears that extended midwifery work in the future must rely largely upon the services of women more elderly than unmarried girls, and in order that these more elderly candidates may have the qualification of literacy it is necessary that they shall have been schooled in their youth. At Tabora school, and at one mission, girls are now being instructed in elementary hygiene and the care of infants, and in later life it may be possible for the services of some of them to be utilized.

School Hygiene—The only reference to this important branch of work appears in the Northern Province Report, viz "Terminal examinations were made of all pupils at Arusha European School and fortnightly visits of inspection were paid to the African Government School at Old Moshi."

Public Health Sanitation etc—Though more funds were available for medical work in 1937 no substantial extension of services was undertaken since all branches of work demanded increased expenditure owing to growing demands and the increased popularity of services. The provincial system of administration (see this Bulletin 1938 Supp. p. 65) is said to be proving its value. It permits a readier exchange of ideas, makes for standardization where this is desirable, and provides better supervision of the smaller units. It is more efficient than a system of direct central control but no cheaper.

The extensive anti-malarial works in progress at Dar-es-Salaam (see this Bulletin 1939 Vol. 36 p. 367 and 1938 Supp. p. 65*) were continued and in all Provinces antimalarial measures figured prominently in the programmes of preventive activities. The Anti-Malaria Engineer visited various stations and at Iringa prepared a scheme for dealing with anopheline breeding places. The need for a sewerage system in Dar-es-Salaam is again emphasized. The bore-hole latrines constructed in the native town have proved unsatisfactory owing to the collapse of the sides due to the sandy nature of the soil. Experiments are being made with various types of lining. Constructional work in connexion with the Tanga sewerage scheme was continued and is expected to be completed in 1938. In Iringa township (Southern Highlands Province) all premises have been provided with latrines. The only references to water supplies appear

in the Laboratory Report. Bacteriological examinations of samples from various sources were made and reported upon. The Dar-es-Salaam supply received special attention with regard to deposits and growths occurring in the mains results of examinations are described and recommendations submitted with a view to improving the supply. *The health of labourers* on sisal estates gave rise to considerable anxiety. The results of examinations of persons who present themselves as potential labourers indicate that a sub-normal state of health from under nourishment and parasitic infection are not uncommon. The state of *nutrition* of the general population received special attention. The investigations of the Committee appointed to report and advise on human nutrition in the Territory demonstrate how incomplete is available knowledge of the problem as it affects Africans in Tanganyika. (The Report of this Committee was published towards the end of 1937). The subject of *native housing* was discussed in an illustrated pamphlet under the title of *Inexpensive Burnt Brick Houses for Natives*. This pamphlet was prepared by Mr A. T. CULWICK (District Officer Ulanga see this *Bulletin* 1938 Supp. p. 71*) published by Government and distributed to officials missions etc. *Legislative measures* enacted during the year in the interests of public health included ordinances concerned with the better control of milk supplies recruitment of labourers anti mosquito work infectious diseases pharmacy poisons lunacy etc.

The education of the public in hygiene continued along lines previously described.

Port Health Work—During the year 1 985 steamers and 4 461 dhows were given pratique at the 12 different ports in the Territory. In June 1937 the regular England South Africa *flying-boat service* was inaugurated by Imperial Airways calls are made at Dar-es-Salaam and Lindi and 258 flying boats were inspected at these ports. *The Air Navigation (Customs Aerodromes) (Amendment) Directions* 1937 add Bukoba and Kigoma to and delete Tabora from the list of customs aerodromes. An air port isolation hospital has been provided at Bukoba.

Hospitals Dispensaries etc—The increasing popularity of hospitals and dispensaries makes a constantly growing demand upon the resources of the Medical Department it is observed that during the year under review 4 921 more in-patients and 23,574 more out patients were treated than in 1936. There are 58 hospitals with bed accommodation for 2 140. European Hospitals are established at ten stations in seven provinces but in ten districts with over 100 Europeans and in two with over 200 there is no European hospital.

A new hospital with accommodation for 25 in patients was erected at Usangi (Northern Province) by the Native Authorities improvements were carried out at the hospitals at Malangali and Mbeya, and improved European accommodation is under construction at Chunya (these three stations are in the Southern Highlands Province).

Arrangements are being made to erect private hospital wards for Africans in some of the larger towns into which only paying patients will be admitted.

There are 38 *Medical Department Dispensaries* and 285 *Tribal Dispensaries* during the year 27 dispensaries were closed and 15 new tribal dispensaries were opened.

The volume of work dealt with at all treatment centres during 1937 may be summarized as follows —

Item	In-patients			Out patients	Tribal Dispensaries
	Admitted	Treated	Died		
Europeans	1 673	1 680	18	3 411	—
Africans and Others	30,807	41 408	2 134	618 179	573,987
Totals	41 480	43 088	2,152	621 590	573,987
Treated by —	1,325	1 395	52	159 801	—
African Dispensaries	2,919	2,930	15	60 078	—
Missionaries					

At the Dodoma and Lutindi *Mental Hospitals* 81 patients were admitted, 28 were discharged one escaped, 42 died leaving 210 in-patients under treatment at the end of the year. At the Dodoma institution 4 new single-bedded wards for males and 6 for females were added during the year but more accommodation is still urgently needed.

Drugs and equipment continue to be supplied by Government to *Missionary Societies* undertaking the care and treatment of the sick and good work continues to be carried out by these bodies. Special mention is made of the maternity and child welfare work carried out by the Church Missionary Society and by the work of the Lutheran Mission in rural areas.

The training of Africans is regarded as one of the chief functions of the Medical Department for it is said that many of the conditions and treatments can be dealt with by trained African personnel at the present time there are not enough educated Africans to meet the demand, but steps are being taken to provide additional educational facilities. Higher grade tribal dressers (*Medical Auxiliaries*) are being trained at five centres where there is accommodation for a total of 60 students, and arrangements have been made for the opening of an additional tribal dresser school at Tanga. The curricula for African dispensers and tribal dressers are given in detail.

Six candidates for appointment as *urban sanitary inspectors* were under training and three were successful at the qualifying examination. Nine candidates are being trained at two hospitals of the Lutheran Mission for rural medical work.

With regard to general *morbidity experience* during the year under review selected diseases are commented upon in the text of the Report while disease incidence in general may be studied from the classified returns. The notes which follow briefly summarize some of the principal menaces to life or causes of disability recorded.

Malaria was responsible for 57,884 cases and of these 5 060 were treated as in-patients and 102 died. The distribution of types of infection reads, *benign tertian* 822, *quartan* 45 *subtertian* 31,272 and unclassified 25 725. Of the total recorded cases 891 occurred amongst Europeans with 2 deaths. 785 were subtertian infections. *Blackwater fever* accounted for 51 cases and 18 deaths ten of the cases and two of the deaths occurring amongst Europeans. Mention has been made

of the anti malarial work in progress (see *Public Health* above). It remains to say that the final reports on Malaria Research of the Malaria Research Officers are in course of printing (see this *Bulletin* 1938 Supp p 67* and 1939 Vol 36 p 126). Provision has been made in the 1938 estimates for the appointment of a Medical Officer of specialized rank to be employed on the investigation and control of mosquito-borne diseases. This officer will assess the value of the measures taken as a result of the recommendations made during the malaria research survey.

Laboratory Reports present the following details of blood films examined during 1937 —

Laboratory	Blood films examined	With malaria parasites
Dar-es-Salaam	2 483	627
Sewa Hadji Hospital (Dar-es-Salaam)	7 094	1 439
Mpwapwa	889	360
Tanga	3,229	936

During the year the following papers on malaria were published —

SPRIS (R. C) Some observations on malaria in the Northern Province of Tanganyika with special reference to immunity. (Submitted as a thesis.)

WILSON (D B) Colonial Development Fund (Malaria Research Scheme) Report of the Malaria Unit Tanga 1933-34 together with the report on a study of malaria in India.

— & WILSON (M E) The manifestations and measurement of immunity to malaria in different races — *Trans Roy Soc Trop Med & Hyg* 1937 Vol 30 pp 41 431-448

Smallpox remains endemic in the Southern Province where 1 462 cases with 28 deaths were reported. Progress was made with the vaccination of the general population and over 102 000 vaccinations were performed. A small outbreak also occurred in Morogoro district (Eastern Province) but was readily controlled and only 9 (non fatal) cases were recorded, the infection being traced to immigrants from the Southern Province. Seven cases were also reported from the Southern Highlands Province with three deaths.

Cases of cerebrospinal fever occurred in every province except the Central and it is said that in the Territory as a whole 265 cases and 125 deaths were recorded. The most serious outbreak was in the Kilosa district of the Eastern Province where between September and November 116 cases and 55 deaths were notified. The infection is believed to have been introduced to some districts by imported labour from the Ruanda Urundi Mandated Territory (where a large scale outbreak was reported) and restrictions were thereupon imposed on recruiting of labour. Arrangements have been made for the provision of a travelling laboratory in order that subsequent outbreaks may receive earlier and fuller investigation on the spot.

Two serious outbreaks of plague occurred during the year the first in the Singida district of the Central Province where 61 cases and 17 deaths were reported. This outbreak was brought under control within a few weeks of the onset in February. The second was a more

Smallpox remains endemic in the Southern Province where 1 462 cases with 28 deaths were reported. Progress was made with the vaccination of the general population and over 102 000 vaccinations were performed. A small outbreak also occurred in Morogoro district (Eastern Province) but was readily controlled and only 9 (non-fatal) cases were recorded the infection being traced to immigrants from the Southern Province. Seven cases were also reported from the Southern Highlands Province with three deaths.

Cases of cerebrospinal fever occurred in every province except the Central and it is said that in the Territory as a whole 265 cases and 125 deaths were recorded. The most serious outbreak was in the Kilosa district of the Eastern Province where between September and November 116 cases and 55 deaths were notified. The infection is believed to have been introduced to some districts by imported labour from the Ruanda Urundi Mandated Territory (where a large scale outbreak was reported) and restrictions were thereupon imposed on recruiting of labour. Arrangements have been made for the provision of a travelling laboratory in order that subsequent outbreaks may receive earlier and fuller investigation on the spot.

Two serious outbreaks of plague occurred during the year the first in the Singida district of the Central Province where 61 cases and 17 deaths were reported this outbreak was brought under control within a few weeks of the onset in February. The second was a more

serious epidemic and was the cause of serious dislocation of trade for some months. The town and port of Mwanza in the Lake Province were first infected climatic conditions favoured the spread of the disease which first appeared in February and continued until August in the Province as a whole 72 cases and 47 deaths were notified. As a result of the outbreak a good deal of reconstruction work was carried out in Mwanza town—rat-proof godowns were built and some slum areas were cleared. Two sporadic and fatal cases were also reported from the Iringa district of the Southern Highlands Province. The Medical Department prepared and distributed Medical Pamphlet No 4 entitled *P plague in Tanganyika Territory*.

At the Dar-es-Salaam Laboratory 2,808 rat spleens were examined for the presence of *P. pestis* all gave negative findings. Typhus is not mentioned in the text of the Report (see this *Bulletin* 1938 Supp. p. 68*) but the classified returns show 8 non-fatal cases 4 of these being treated as in-patients. Of relapsing fever 1,612 cases were reported 504 were hospital in-patients and 17 died. No case of yellow fever was recorded. The usual *Aedes* index table is presented it being stated that the figures for Dar-es-Salaam may be accepted with some confidence though the figures for other towns are of little comparative value.

One hundred and five cases of typhoid and twelve of paratyphoid fever were treated during the year. 83 of the typhoid and all the paratyphoid cases were treated as in-patients with 21 deaths (20 due to typhoid). The centres showing the largest number of enteric cases were Morogoro (Eastern Province) 33 with 6 deaths, Tanga (Tanga Province) 11 with 4 deaths and Mwanza (Lake Province) 8 cases 5 deaths. 4 non-fatal cases of paratyphoid were also treated at Mwanza. At the Main Laboratory Dar-es-Salaam where 260 samples of blood serum were examined 81 agglutinated *Bact. typhosum* 6 *Bact. paratyphosum* 4 *Bact. paratyphosum B* and 3 showed both typhoid and paratyphoid infections. Dysenteric cases numbered 1,918 of which 793 were amoebic. 185 bacillary and 950 unclassified infections. Of the total cases recorded 525 were treated as in-patients and 51 died.

Mention has been made of the attention devoted to problems of nutrition (see *Public Health* above). In the Morogoro District of the Eastern Province *nutritional diarrhoea* assumed somewhat serious proportions and during the year 174 cases with 108 deaths were reported. Sufferers were mainly imported labourers on the local sugar estates. Factors responsible for the condition included, recruits of poor physique unsuitable diets, poor housing, and inadequate medical facilities. Steps have been taken to deal with these matters and bring about improvement. In the Lupia Goldfields area (Southern Highlands Province) 383 cases of scurvy were reported but only one death was ascribed to this cause. At the Tabora Hospital (Western Province) 43 cases of beriberi were dealt with while in the Territory there were 63 cases and 3 deaths due to this condition.

The incidence of *elephantiasis* continues to diminish (see this *Bullet.* 1938 Supp. pp. 68–69*). During the year 300 new cases were reported 168 of these from the Western Province alone. In the Central Province (6 new cases) the systematic clearing of bush was

continued and 17½ square miles cleared during the year. From the Lake Province 51 new cases were reported. The 1936 outbreak in the Southern Province appears to remain circumscribed. 75 new cases were reported but it is not claimed that all cases are reported. A general survey is being carried out in preparation of closer control of the disease in the affected area. In the Western Province about 1 500 families were moved into new concentrations and about 150 other families moved into old settlements (see this *Bulletin* 1938 Supp p 68*). The incidence of the disease continues to decline. 168 new cases were recorded.

The research work of Dr J F Corson at Tinde continues (see this *Bulletin* 1938 Supp p 69*) while observations were carried out by Mr Eric BURTT on the ability of *Glossina brevipalpis* to transmit *T. rhodesiense* biologically. The titles of papers published on trypanosomiasis research include the following—

CALWELL (H G) The pathology of the brain in Rhodesian Trypanosomiasis—*Trans Roy Soc Trop Med & Hyg* 1937 Vol 30 No 6 pp 611-624

CORSON (J F) Are experiments with trypanosomes in laboratories in tropical Africa vitiated by accidental infection?—*Trans Roy Soc Trop Med & Hyg* 1936 Vol 30 No 3 pp 304-312

Experimental transmission of *Trypanosoma gambiense* by *Glossina morsitans* through monkeys—*Ann Trop Med & Parasit* 1936 Vol 30 No 4 pp 339-400

The infectivity to man of a strain of *Trypanosoma rhodesiense* transmitted through sheep by *Glossina morsitans* and its resistance to human serum *in vitro*—*Ann Trop Med & Parasit* 1937 Vol 31 No 2 pp 285-291

Tuberculosis (all forms) was responsible for 3 056 cases with 166 deaths. 2 109 of the cases and 152 of the deaths were due to the pulmonary form of the disease. Of the total cases and deaths recorded 2 116 cases and 25 deaths occurred in the Northern Province. 1 370 of the Northern Province cases and 21 of the deaths being due to the pulmonary form of the disease. At Kibongoto in the Northern Province the first section of the Tuberculosis Village Settlement was brought

of two Missions receiving assistance from Government. At the Main Laboratory Dar-es-Salaam where 182 nasal and skin smears were examined 97 were positive with *Myco leprae* and at the Tanga Laboratory where 31 nasal smears were examined 22.5 per cent gave positive findings.

Veneral diseases—At Government institutions 23,374 cases of *syphilis* were treated but if cases treated at Mission centres are included the total becomes 31,348. Of *gonorrhoea* 10,712 cases were recorded and of other veneral diseases 1,725. Work is being continued on the differential diagnosis of veneral diseases at a number of centres. Cases of *yaws* treated at Government institutions and Missions totalled 110,819 and of this total 73,822 cases were recorded at Government institutions. Florid *yaws* is said to be frequently met with in some districts of the Southern Province. At the Main Laboratory Dar-es-Salaam 755 specimens of serum were Wassermann tested, 220 gave positive and 40 doubtful reactions. 785 Kahn tests were carried out with positive results in 224 and doubtful findings in 48 cases. At the Tanga Laboratory 49 per cent of the 253 Kahn tests gave positive results.

Scientific—In the appropriate sections above brief mention has already been made of the special research work carried out in connexion with *malaria*, *trypanosomiasis* and *tuberculosis*. So far as the four Laboratories are concerned continued staff shortage and the large increase in the volume of routine work during the year precluded any possibility of research work being undertaken though the Government Analyst Mr W. D. RAYMOND succeeded in continuing his investigations into arrow poisons, native drugs, etc. It is pointed out that there remain innumerable minor though important field problems of a local nature capable of solution by workers with experience of local conditions but such problems will continue unsolved while laboratory facilities are limited and laboratory staffs inadequate. In this connexion it is interesting to note that a mobile laboratory at present under construction will be equipped to deal with common bacteriological investigations at short notice. This service should prove invaluable provided a full time pathologist is appointed to conduct it.

During the course of the year 38,891 specimens were examined in the Laboratory and Research Division—an increase of 10,234 over the 1936 record of work. The more important specimens dealt with and findings recorded have been quoted under various headings in the preceding summaries of morbidity experience. It remains to say that on 1 March 1937 a clinical laboratory was established at Tanga and by the end of the year over 10,000 specimens had been dealt with these including 253 Kahn and 26 Widal reactions. The value of trained Africans is well illustrated at the Tanga Laboratory where the African in charge trained at the Dar-es-Salaam Medical School and General Laboratory is doing excellent work under the supervision of the Senior Medical Officer.

Financial—Total expenditure on Medical Services for the year under review amounted to £201,280. In addition the Colonial Development Fund provided £721 for the Tuberculosis Investigation, £2,640 for Sleeping Sickness Research and £3,203 for the Anti Malaria Works Dar-es-Salaam.

"the mental distress caused to patient and relatives by needless infringement of the taboos only adds to the reluctance of village women to seek help or enter the hospital," etc. Native midwives are allowed to be present at deliveries of their patients in the hospital, thus permission it is said, has done much to remove the antipathy of these professional African practitioners who might naturally be expected to be suspicious of and to resent anything which would lead to the loss of their means of livelihood, i.e. midwifery fees, while it is hoped that as observers they may acquire knowledge of European midwifery methods.

Government continued to collaborate with and subsidize the Missions undertaking maternity and child welfare work. At the centre maintained by the Church of Scotland Mission at Blantyre four women were trained as midwives during the year and two new infant welfare centres were opened. Native midwives are also trained at the Vlanda Centre of the Dutch Reformed Church. Eight girls are in training at Bandawe and at the infant welfare centre 3,805 attendances were recorded.

The figures below summarize the volume of work carried out at centres other than the African Hospital, Zomba, subsidized by Government—

	Mlanda Mission	Blantyre Mission	Jessies Centre
(1) Infants registered at Welfare Centres	532	208	48
(2) Confinements conducted	118	437	73

School Hygiene.—All European schools were inspected during the year and general health conditions of the pupils reported to be satisfactory. With regard to African schools it was hoped that at least one such school in each district would be examined during the year but the pressure of routine work prevented this program from being carried out, and only a small percentage of the schools were visited and 731 children medically examined. The Report under review describes the results of inspections carried out at five African schools—

The Central School Haronga where 251 boys and 38 girls were examined. Two early cases of leprosy were discovered.

Providence Girls School Mlango.—A high incidence of helminthiasis among the 167 pupils examined.

Kaura Mission School Dedza.—General improvement in physical condition etc. among the 108 pupils examined, due to adequate dietary and attention paid to personal hygiene.

Mission School Mlondos Fort Johnston.—Latrine accommodation insufficient. Pupils examined 107. Latrine accommodation given where necessary.

Catholic Institute Blantyre.—No considerable improvement noted in the condition of the 60 pupils examined.

The results of Medical Surveys (see hereafter *Public Health* also this Bulletin 1937 Supp pp 63-64 and 1938 Supp pp 72-73 76)

are presented in detail in a series of Tables in the Report under review. Results are assembled from seven areas in the Protectorate in three age-groups the first of which relates to children aged 0-10 years. haemoglobin estimations the results of blood film spleen urine and stool examinations are among the data tabulated.

Public Health Sanitation etc—Under the heading of Public Health Dr. Bedward Williams contributes an admirable account of the historical development of the health services of Nyasaland, reviews the work performed by the Medical Department and progress made during the past 25 years, and submits recommendations for the future development of public health work in the Protectorate. This valuable section of the Report should be read in its entirety for limits of space in this *Supplement* prohibit the adequate summary which the contribution merits.

With regard to the work of the Department generally it is said that there is little that is new to record. In the larger townships the disposal of night-soil and rubbish has been satisfactorily dealt with, water supplies installed, drainage schemes carried out and other sanitary improvements effected. But in the rural areas difficulties of a very special nature are encountered while the lack of trained sanitary staff European and African tends to retard progress. Nevertheless that the arduous and self-sacrificing efforts of Medical Officers have in many instances been successful in bringing about notable improvement in several areas is evident from the extracts quoted from the reports of Medical Officers as for example—

Fort Johnston—A determined effort was made to commence the important task of rendering the natives really used to the idea of latrines as part of their ordinary life and not a meaningless ritual forced upon them. The idea was to have finally a latrine for every hut. No labour was provided. No compulsion of any kind was used. explanatory talks were given.

Nearly 200 latrines are in use and construction is still going on.

Dedza—The degree with which advice has been followed with regard to sanitary matters varies in direct proportion to the character and capability of the Native Authority concerned. Kachindamoto's area is the most satisfactory. A mass bookworm campaign was carried out. A propaganda meeting was attended by some 300 natives.

Dowa—Of Sendeza it is said. Some sanitary work has been done. The village headman is helpful and the local school teacher helps him. New houses constructed and latrination is complete.

Kola Kola—Vaccinators have done good work in rural sanitation.

Of the Protectorate as a whole it is noted that increased attention has been given to the protection of water supplies and that the boring of wells has been undertaken by the Geological Department.

The objects envisaged by the *Medical Surveys* to which reference has been made above and in previous issues of this *Supplement* are (a) to bring Medical Officers into closer contact with village life and (b) to obtain by actual examination of the inhabitants of selected areas a knowledge of the population, births, deaths and morbidity etc. of such areas. These surveys have proved conspicuously successful and during the year under review enquiries were carried out in seven areas. In three areas it was found possible

to undertake surveys (a) among villagers resident at lake level, and (b) among others living at an altitude of over 3 000 feet. The results of these investigations are set out in three age-groups in a series of Tables (see above also *School Hygiene*) together with the commentaries on results by the Medical Officers conducting the surveys. The report of an additional survey conducted at the Jeanes Training Centre is dealt with separately as it relates to natives from many districts.

Inspections of labour conditions on estates were continued these visits have been instrumental in bringing about general sanitary improvements. The emigration of adult males to the Rand mines continues (see this *Bulletin* 1937 Supp p 65* and 1938 Supp p 75) with serious results so far as native social life is concerned—there is a lack of fit adult males for carrying on the routine work characterizing the daily lives of the people while returning emigrants bring with them the seeds of disease. While measures have been taken for the better care of repatriated labourers arriving in Niasaland, no information is available of the thousands of returning emigrants who do not present themselves for examination.

Housing and Town Planning schemes and *Food in relation to Health and Disease* are subjects of comment (see this *Bulletin* 1938 Supp p 75). Replies to the questionnaire on nutrition drafted by the Health Department and submitted to District Commissioners to Missions and certain educated Africans, and to Medical, Agricultural, and Forestry Officers were analysed and the results tabulated and embodied in a Memorandum presented to and adopted by the Native Welfare Committee. This Memorandum appears as an Appendix to the Report under review under the title of *A Review of the Present Knowledge of Human Nutrition in Niasaland*.

The scheme for the training of Africans had to be modified considerably owing to sickness among the nursing staff (see this *Bulletin* 1938 Supp p 76*). At the African Hospital, Zomba provision is made for the training of various grades of African personnel, male and female while at the Jeanes Centre the training of welfare community workers is undertaken.

Measures taken to spread the knowledge of Hygiene and Sanitation continued to be energetically implemented.

Recommendations and Proposals for Reorganization and Future Development of Health Services are discussed at considerable length (see also this *Bulletin* 1938 Supp p 73).

Port Health Work—The quarantine camp at Port Herald on the Beira Blantyre Railway continued to function during the year. 71 Africans were detained for vaccination, having been in contact with infectious disease etc.

Hospitals Dispensaries etc.—At present there are six Hospitals each with 50 or more beds, and nine with 30 beds. It is recommended that three of the 50-bed hospitals should be increased to 100 beds each with augmented staffs and equipment and that the 30-bed units might have accommodation reduced to 15 beds and be placed in the charge of African hospital assistants. Financial considerations render the construction of a new hospital at Zomba impossible. In the Northern Province the non-official European community provided the funds for the construction of a small cottage hospital at Lilongwe.

Government will maintain and staff this unit. As regards *native hospitals* no new buildings have been erected nor have any additions been made to existing institutions. There is a growing demand from the Native Authorities for the provision of additional *rural dispensaries*. During the past two years upwards of 23 applications were received for new dispensaries in some cases Native Authorities have provided the funds for the erection and maintenance of these units. The volume of work dealt with at hospitals and dispensaries during 1937 may be summarized as follows —

Race	Hospitals			Dispensaries Out patients
	In-patients	Deaths	Out patients	
Europeans	223	7	1,215	—
Africans and others	10 595	270	113 669	302,318

The commentaries upon general morbidity experience contained in the Annual Report under review are briefly referred to in the notes which follow.

Cases of *malaria* dealt with at hospitals and dispensaries totalled 15 774 the distribution by race and types of infection being as follows —

Type of Infection	Europeans		Africans and Others		Rural Dispensaries Out patients
	In-patients	Out patients	In-patients	Out patients	
Benign tertian	5	11	92	189	—
Quartan	—	1	32	113	—
Subtertian	2	41	527	717	—
Cachexia	—	1	46	50	—
Blackwater	—	2	—	—	—
Undefined	18	82	354	3 762	9 729
Totals	25	138	1 051	4 831	9 729

There were 22 deaths among Africans due to malaria and 2 cases of *blackwater fever* with 1 death among Europeans. The Government Entomologist has pointed out that although *A. costalis* is almost absent during the dry season it is overwhelmingly abundant during the late rains while the other common species *A. funestus* shows no numerical increase during the year. He also found that the infection rate among *costalis* was very much higher than in *funestus*. The usual *anti-malarial measures* were successfully employed and it is reported that as a result the mosquito nuisance has been abated to a large extent in some areas.

At the Government Laboratory Zomba 1,379 out of 4,827 blood films examined were found to contain malaria parasites the positive findings being *P. falciparum* 1154 *P. malariae* 189 and *P. vivax* 36. The reports of the Medical Surveys (see above) present the results of

blood film and spleen examinations at high and low altitudes in various areas.

Only 88 (non-fatal) African cases of *smallpox* were reported during the year 1935. Vaccinations were performed.

A somewhat serious epidemic of *cerebrospinal meningitis* occurred in the Southern Province and necessitated the promulgation of special rules under the Public Health Ordinance for the control of the movements of natives etc. The first case occurred in August and spread was rapid—altogether 780 cases were reported and of this total 603 occurred in the Mlanje District. Dr W. T. C. BERRY, the Medical Officer, recorded for special duty in connection with the epidemic contributes a detailed report which is presented as an Appendix to the Report under review.

Of *relapsing fever* 139 cases were notified. Of the total cases recorded 51 were dealt with in the Kota-Kota district alone where most of the cases gave a history of having slept in Government rest-houses—the importance of having these rest-houses constructed of vermin-proof materials is emphasized. The Medical Officer, Kota-Kota, also reports among the results of his *Medical Surveys* in the area the carrier of *relapsing fever* is to be found in every hut.

Only one (non-fatal) African case of *ariens fever* appears in the Hospital Returns, but 1,538 cases of *dysentery* were treated during the year and of these 62 occurred among Europeans. The distribution of types of infection was (a) *Europeans* amoebic 66, undefined 6, and 1,296 faecal specimens examined at the Government Laboratory 83 were positive for *E. histolytica*.

Tuberculosis is considered to be increasing though it is not known even approximately what the incidence of the disease really is. Of the 231 cases reported during the year 145 patients were suffering from the *pulmonary* form of the disease. Out of a total of 252 Nyasaland native labourers repatriated from Southern Rhodesia during the year 89 were stated to have had tuberculosis and of these 35 were said to have suffered from phthisis. With a view to obtaining more accurate information concerning the incidence of the disease surveys were carried out in three areas, and among 344 children examined by the dermal method using Moro's tuberculin ointment 31 gave positive reactions. It is said to be practically impossible to keep African patients in hospital for periods long enough to treat the disease effectively.

Of *ly. phlebotomus* only two cases were reported—both from the Kota-Kota district. The medical Entomologist, Dr W. A. LAMBORN, reports that the steady retreat of the tsetse in a northerly direction continues—he estimates that the flies have vacated approximately 400 square miles of country since 1927. Dr Lamborn discusses the probable causes which have brought about the continued diminution of the numbers of flies, and concludes that the decline must be due largely to the dearth of animal life on which the insects depend for their food—the opening up of large estates, shooting, organized hunts by natives etc.—have all played their part in scaring game animals which have withdrawn to the Reserve in the North. A survey for parasites of the tsetse was commenced with a view to determining to

what extent they may be responsible for the steady decline in the numbers of fly but first results suggest that parasites do not play an important part in bringing about the observed reduction

Helminthiasis—The following data relating to patients treated for helminthic diseases have been extracted from Hospital and Dispensary Returns—*ankylostomiasis* 12,242 cases *ascariasis* 2,231 *taeniasis* 161 *schistosomiasis* 7,487 and other helminthic diseases 342 giving a total number of 22,463 cases dealt with. These figures refer to Out patients only. It would appear that either in patient cases were first seen as out patients and not regarded as new cases if afterwards admitted to hospital or in-patient cases have been omitted in error from the total in the Report under review. The text of the Report specifically states 'The total number of cases treated was 22,463'. But in addition to the 22,463 out patients there were 1,845 non European in-patients and one European in-patient. The results of stool and urine examinations carried out in the course of *Medical Surveys* in various areas are presented in a series of tabular statements together with the commentaries of Medical Officers in charge of these investigations. The Medical Officer in charge of the survey of the North Nyasa District commenting on the high incidence of *schistosomiasis* in the area surveyed observes—

In this marsh *B. africanus* is prevalent. *Limnæa* were also found but in a search extending along the Lake shore from the River Songwe to Deep Bay (approximately 50 miles) I did not see a single *Planorbis*. It would appear that this mollusc is not the carrier of the disease in this district and another snail must be concerned.

In an Appendix to the Report under review Dr W. L. GOPSILL contributes an interesting account of the incidence in this area under the title of *Some Observations on Schistosomiasis in North Nyasa District*.

At the Government Laboratory among 1,078 specimens of urine examined 219 contained evidence of bilharzial infestation while the findings among 1,396 faecal specimens dealt with included *ancylostoma* 520 *ascaris* 27 *S. mansoni* 37 *E. histolytica* 88.

Of venereal diseases 3,324 cases were reported and of these 2,377 cases were of syphilis and 947 gonorrhoea. The out-patient clinic at Blantyre continued to function with fair success but subsequent attendances following first visits for treatment were disappointingly few. It is noted that a native nurse was posted to the clinic and 145 female patients paid a first visit. At Denza among 1,435 labourers examined only 28 were rejected on grounds of venereal disease. The finding is interesting in view of the common belief that venereal diseases are increasing. Hospital and Dispensary Returns also show that 2,960 cases of yaws were treated during the year under review.

Leprosy—The treatment of the disease in Nyasaland is carried out almost entirely by the Missions with the financial aid of Government. There are 12 clinics established throughout the country, the majority of the centres being in charge of qualified nurses. Approximately 648 lepers were under treatment at these clinics during the year 260 were admitted 96 were discharged, and 35 died. It is not known to what extent the disease is prevalent in Nyasaland, but it may be possible to obtain fairly dependable information during the course of the next census.

Among other diseases mentioned in the Report deficiency diseases were the subject of special investigation by the Medical Department the results of the enquiry being embodied in a Memorandum presented to the Native Welfare Committee (see above *Public Health*). Five cases of rickets 3 of scrovy 5 of beriberi and 48 of pellagra were recorded during the year. Rabies is said to have caused anxiety and to have "shown no signs of abatement" but no cases appear to have been recorded unless they have been included under the title "Injuries inflicted by animals (bites, kicks, etc)". Over 50 000 cases of ulcers among African patients and 43 781 cases of bronchitis were dealt with.

Scientific—The Report of the Government Pathologist is confined to a summary of the specimens received and examined at the Government Laboratory and findings recorded. Altogether 8 058 specimens were dealt with the principal findings have been referred to in preceding sections of this summary. The Annual Report of the Medical Entomologist has also been quoted in the section (*trypanosomiasis* above. In addition to the tsetse fly surveys, Dr Lamborn continued his survey for rodents and their ectoparasites and his investigations of the breeding habits of *Tabanidae* and commenced a study designed to determine whether *Myco tuberculosis* undergoes any morphological changes within the fly *Musca sorbens* and whether the organisms remain viable after they have been ingested by the fly.

Four Special Reports appear as Appendices to the Report under review viz:—

- (1) Post-Operative Complications in the Natives of Nyasaland, by Dr C H. HOWAT
- (2) Cerebrospinal Fever in Nyasaland by Dr W T C BERRY (Reviewed in *Bulletin of Hygiene* 1938 Vol 13 p 867)
- (3) Some Observations on Schistosomiasis in the North Nyasa District, by Dr W L GOSALL (Reviewed in this *Bulletin* 1939 Vol 38 p 33)
- (4) The Native Welfare Committee Report on Nutrition (Reviewed in *Bulletin of Hygiene* 1938 Vol 13 p 931)

Three of these Special Reports have already been the subject of brief reference in the preceding notes. It remains to say that Dr Howat's contribution discusses four common complications of operation viz post-anaesthetic vomiting infection of the surgical wound, retention of urine and pulmonary lesions—bronchitis, pneumonia etc. His surgical practice in Nyasaland leads him to conclude that these complications are encountered rarely or not at all in the Protectorate.

Financial—Actual expenditure on Medical Department services during 1937 amounted to £51,322 as against an approved expenditure of £52,712.

ZANZIBAR PROTECTORATE (1937)

Zanzibar Protectorate off the East African Coast comprises the islands of Zanzibar and Pemba and the islets within their territorial waters. Zanzibar is about 53 miles long by 24 miles broad with an area of 640 sq miles. Pemba to the north-east of Zanzibar is about 42 miles long by 14 miles broad. The only town of importance is Zanzibar Town.

Vital Statistics—Published figures are compiled from returns submitted by the *Mudirs* through the Provincial Administration and in the words of the Report cannot be regarded as even approximately correct for registration is incomplete. The principal facts are given as follows —

Estimated Population	Registered Births	Birth Rate	Registered Deaths	Death Rate
243 135	4 139	17.0	4 026	16.9

The *infant mortality rate* for the year is not stated but it is observed that rates in specially defined areas in 1937 were 141 for natives and 159 for Indians per 1 000 live births. The *maternal mortality rate* of 9.2 per 1 000 live births relates principally to the town of Zanzibar for the Protectorate as a whole it is believed this rate would be greatly exceeded. The investigations of the Welfare Clinic are being continued and it is hoped that by the end of 1938 sufficient data will have been assembled to provide reasonably dependable infant and maternal mortality rates.

European Officials resident numbered 110 with an average number resident of 70. One death was recorded. *Non European Officials* resident numbered 462 with an average number resident of 423. Five were invalided but no deaths were recorded in this group.

The most common causes of sickness amongst Europeans and Non European officials were *influenza, malaria and diseases of the respiratory and digestive systems*.

Maternity and Child Welfare Work.—The year 1937 saw the results of the first full year's work of the Lady Medical Officer and her staff (see this *Bulletin* 1938 Supp. p. 81*). During the year the 7 310 new patients registered at the special day clinics made 45,308 attendances for treatment of special significance is the fact that the proportion of women in Zanzibar attending hospitals for treatment rose from 22 per cent in 1935 to 40 per cent in 1938 (when the clinic started) and to 59 per cent in 1937. In the Pemba Hospitals where there is no woman doctor the proportion of women patients has remained roughly constant at 23 per cent. The striking success of the venture in Zanzibar will be followed by the appointment of a second woman doctor in 1938 with extension of similar activities to the island of Pemba and to rural areas in the Protectorate when financial resources permit. Meanwhile at the hospitals at Chake Chake and Wete in Pemba a start has been made by providing women's out-patient departments separated as widely as conditions permit from the men. In commenting upon these new departures and of the success of the initial venture in Zanzibar Dr W Leslie WEBB, Director

of Medical Services, quotes from the memoirs of one of the daughters of the first Sultan of Muscat and Zanzibar and published in 1880 in which the enlightened lady observed that if a female physician could be brought to undertake service in Zanzibar she would be able to do more good than ten medical men combined.

At the three *Infant Welfare Clinics* held weekly attendances totalled 3 812 and at the *Adult Natal Clinic* 817. During the year under review cases of diseases of the *puerperal state* dealt with in Government Hospitals numbered 302 as compared with 115 in the preceding year. Clinics were also actively functioning during the year at four rural dispensaries with encouraging results.

The *Zanzibar Maternity Association* is no longer under the control of the Medical Department (see this *Bulletin* 1937 Supp p 70* and 1938 Supp p 81) and returns of the work of that organization will no longer be included in the Annual Medical Report.

School Hygiene—A most satisfactory feature of the year's work was the extension of the School Medical Service. During 1937 over 1,800 children were medically examined and nearly 1,300 were seen by the Dental Surgeon—the largest numbers of school-children ever dealt with in a single year in the Protectorate. The service is well established in both islands and fewer difficulties are met with for examinations are willingly accepted by both parents and children. The results of these examinations are set out in considerable detail in the Report under review but for present purposes it must suffice to summarize briefly the principal findings. In both Zanzibar and Pemba malnutrition is grossly evident amongst rural African children, less so among rural Arabs. The town-dwelling African child, less so town Arab child. Malnutrition is less evident amongst pupils at the Government girls' school than amongst male children. With one or two exceptions the cleanliness of school-children leaves much to be desired—scabies is common in the rural schools owing to the filthy condition of the cotton garments worn by pupils. In all schools dental caries is very common—the rural areas with *ascariasis* common defects being most common in areas where malnutrition is evident. *Angiodysentria* is said to be universal in the rural areas and *syphilis* has regularly been carried out treatment for warts and *syphilis* has produced satisfactory results but for ankylostomiasis results have not proved so encouraging.

owing to the frequency with which re-infestations occur. Lectures on health subjects are given to school-children special attention being devoted to talks on the dangers of hookworm malaria scabies, etc. and how these diseases may be avoided.

Public Health Sanitation etc.—Dr W. Leake Wynn observes Adequately trained native staff still remains one of the crying needs of the department and it is difficult to see how any material extension of service can be effected without considerable cost until it is provided. In 1935 Government approved a scheme for the formation of a Zanzibar Native Medical Service through the framework of which rural Africans could be given a comprehensive training in medical work with a view to subsequent absorption into the Department as

rural dispensers nurses and midwives. However at that time there were no rural Africans of the required educational standard available for training though subsequently with the co-operation of the Education Department arrangements were made for the further general education of a number of boys and girls the first of these classes of boys will be available for Medical Department training in 1940 and of girls in 1942.

The anti malarial survey conducted by Dr D D McCARTHY (see this *Bulletin* 1938 Supp p 84*) under a grant from the Colonial Development Fund was completed in September 1937 and it is expected that his Report will be published early in 1938. Preventive measures continue to be actively carried out along the lines described in previous issues of this *Supplement*.

Present-day methods of *sewage disposal* were described in earlier Reports and referred to in this *Bulletin* 1937 Supp p 72* and 1938 Supp p 82*. The posting of three locally trained African Sanitary Inspectors for permanent employment to rural areas in connexion with a scheme for providing *bone hole latrines* for the whole population in those areas marks the first serious attempt to cope with the problem of rural sanitation. Scavenging services and methods for the removal and disposal of refuse continued along lines previously described.

In Zanzibar *water supplies* were ample and satisfactory where water-mains are laid but in the native town the population have to employ water carriers to bring water to their houses. In Pemba supplies to Chake and Wete were reasonably satisfactory but in Mkoani water is of poor quality and insufficient in quantity. The Public Works Department have carried out experimental borings and it is expected that the present unsatisfactory conditions will shortly be remedied. In rural areas water is still obtained from deep and shallow wells and from rivers. Sanitary Inspectors are required to supervise and endeavour to improve supplies in such areas.

Under the heading of *Housing and Town Planning* a somewhat detailed account is provided of general conditions and of attempts to bring about improvement so far as urban housing is concerned in Zanzibar and Pemba. Numerous surveys and inspections of properties brought to light many cases of unsatisfactory housing and steady pressure was maintained to persuade or enforce owners to effect necessary improvements. Rural housing conditions did not alter during 1937 it is said that though on the whole rural housing is not good there is little overcrowding.

As regards *foods etc* it is stated that the publication of a *Nutritional Review of the Natives of Zanzibar* early in the year served to focus attention on the subject for it was clearly demonstrated that native dietaries are invariably lacking in some essential foodstuffs to the detriment of the health of the people. The implementation of the recommendations made for the improvement of existing conditions must be a matter of time and governed largely by financial considerations (see also this *Bulletin* 1937 Supp p 72* and 1938 Supp p 83*).

Training of Native Personnel—A notable advance in the training of non European personnel was made when the systematic training of some learner Sanitary Inspectors (Indian, African and Goan) culminated in their examination under the auspices of the Royal Sanitary

Institute five satisfied the examiners. The training scheme is the first of its kind to be undertaken in East Africa. The training of rural dispensers was continued as usual.

Measures taken to spread the knowledge of hygiene and sanitation included lectures by Sanitary Inspectors to school-children and the general population the distribution of pamphlets devoted to explaining the meaning of simple health precautions lectures by Medical Officers, Health Exhibitions, etc.

The *Annual Report of the Dental Surgeon* is printed as an Appendix to the Annual Medical Report under review. It is stated that after four years of observation of the natives of Zanzibar Protectorate it is safe to affirm that over 90 per cent. of them suffer from dental disease. The Report comments at some length on oral conditions in the Protectorate discusses dental work carried out among school-children and supplies tabulated facts relating to the numbers of schools visited, pupils examined, etc.

Port Health Work—During the year 588 ships and 712 dhows entered the harbour and 1,531 immigrants landed. Routine services were carried out as usual, and nothing unusual in respect of Port Health work is reported.

Aeroplane traffic accounted for the arrival and departure of 347 planes carrying 384 immigrants and 267 emigrants. All aircraft arrive from Kenya or Tanganyika no quarantine restrictions of any kind are imposed and so far do not appear to be called for.

Hospitals Dispensaries etc—The numbers and distribution of Hospitals and Dispensaries in the Protectorate may be conveniently set out in the following manner—

Locality	Hospitals	Special Clinics	Dispensaries	Totals
Zanzibar Island —Town	4	2	2	10
District	2	—	19	21
Pemba Island —Town	2	—	—	2
District	1	—	7	8
Totals	12	2	28	42

The above figures include one European hospital and a Mental Hospital in Zanzibar Town, a Poor Home and a Leper Colony in Zanzibar District, and a Leper Colony in Pemba Island District.

At these institutions 4,673 in-patients were admitted during the year in-patient cases treated totalled 5,197 and 478 hospital deaths were recorded. Out-patients dealt with numbered 121,347 and among them 448,370 attendances were recorded, 219,398 being attendances at Dispensaries. Mention has already been made of the extension of medical facilities in the interests of women (see *Maternity* above) and of the proportions of female to male patients attending for treatment.

The only figures of value throwing any light on the incidence of disease in the Protectorate are the returns compiled at Government Hospitals and Dispensaries. The following notes briefly summarize the principal references contained in the Report under review to disease incidence during 1937.

Malaria patients treated at Government Hospitals etc. numbered 8,801 and of these 249 were in patients (7 died) and 8,552 were out patients. The distribution of types of infection among in patients reads *benign tertian* 28 *quartan* 1 *subtertian* 123 and unclassified 97 the corresponding figures for out patients being 457 22, 1,797 and 6,278 respectively. There were also 5 cases of *blackwater fever* two of these being treated as in patients. At the Pathological Laboratories Zanzibar and Pemba the following blood films were examined and findings recorded —

Laboratory	Blood Films	Positive findings			
		<i>P. vivax</i>	<i>P. falciparum</i>	<i>P. malariae</i>	Undefined
Zanzibar	9,378	253	1,252	26	563
Pemba	2,013	446	339	—	108

P. vivax and *P. falciparum* were found together in 22.

Reference has been made in the section *Public Health* above of antimalarial control measures and of the special survey completed in 1937.

No case of any of the dangerous infectious diseases was recorded (see this *Bulletin* 1938 Supp. p. 84*). During the year 8,805 anti-smallpox vaccinations were performed in Zanzibar and 1,918 in Pemba. One case of *relapsing fever* was reported but as *O. moubata* is not known to exist in Zanzibar or Pemba it is certain the disease must have been contracted outside the Protectorate. One fatal case of *cerebrospinal meningitis* was notified from Wete in Pemba.

Of the 22 cases of *enteric fever* notified 20 occurred in Zanzibar Town. At the Zanzibar Laboratory 18 out of the 113 samples of serum agglutinated *Bact. typhosum*. *Dysentery* was responsible for 58 cases and of these 36 occurred in Zanzibar (Hospital Returns record 61 cases of which 6 were amoebic, 24 bacillary, and 31 unclassified.) Among 142 faecal specimens examined *Bact. dysenteriae* Flexner was isolated in 26 and Sonne in 6.

During the year 214 patients were treated for *tuberculosis* (all forms) and of this total 182 were suffering from the *pulmonary* type of the disease. 45 of the 48 deaths were due to phthisis. New cases notified, nearly all of the *pulmonary* type, numbered 151 and of these 125 were in Zanzibar Island. The year's figures for the Walezo Tuberculosis Asylum were total treated 94, died 33, discharged 39. There were also 6,454 cases of *bronchitis* and 204 of *pneumonia*.

New cases of *leprosy* notified numbered 28 and the total cases treated 137. The two Leper Colonies at Walezo in Zanzibar and Makondeni in Pemba are well patronized by lepers who enter and reside there voluntarily (see this *Bulletin* 1938 Supp. p. 84*).

Helminthic diseases—Hospital Returns show that 12,202 cases of *ankylostomiasis* were dealt with during the year. The view is expressed that there can be no doubt that nearly the whole population of the island of Zanzibar is infected with hookworm. In an attempt to discover to what extent the application of proved methods of control is applicable in Zanzibar Government is to provide sufficient latrine accommodation in a selected area and by the end of the year six boring

machines were at work in the area under the charge of three African Sanitary Inspectors. Efforts are being made to popularize the use of latrines by constructing bore-hole latrines and providing cement tops free of charge at a cost to Government of 4 shillings each complete latrine and if the experiment proves successful it is hoped to apply the principle to the whole Protectorate. *Schistosomiasis* is said to be widespread in Pemba but less evident in Zanzibar intestinal forms of the disease are rare. During the year 578 cases were treated. An investigation of the problem was undertaken by a research worker from the London School of Hygiene and Tropical Medicine and by the end of the year the small carrier had been incriminated, and the fact ascertained that its distribution in the Protectorate is limited by certain definite factors. In the light of these discoveries it is hoped that measures may be devised for the complete eradication of the disease. At the two Laboratories the following findings were recorded following the examination of specimens of faeces and urine —

Item	Laboratory	
	Zanzibar	Pemba
Faecal specimens examined	6,328	868
Positive findings —		
<i>Ancylostoma</i>	2,608	408
<i>Ascaris</i>	433	29
<i>Trichuris</i>	842	48
<i>S. mansoni</i>	5	—
Urine examined	499	813
Positive findings —		
<i>S. haematobium</i>	162	129

Veneral Diseases — During the year 1 062 cases of syphilis 1 485 of gonorrhoea 65 of soft chancre and 4 183 of yaws were treated. It is stated that the figures for gonorrhoea give no idea of the incidence for almost every adult has the disease (see this *Bulletin* 1938 Supp p 85*). At the Zanzibar Laboratory the hahn test applied to 4,210 samples of serum gave 684 positive and 592 doubtful reactions.

Other diseases referred to in the Report included the following. It is said that *filaria* occupies a prominent position amongst diseases affecting natives. For ulcers 21,873 cases were dealt with. Among the 3,354 diseases of the eye treated were 83 cases of trachoma. Cases of *influenza* numbered 1 098 all were of a mild type and no deaths were reported.

Scientific — The Laboratories at Zanzibar and Pemba continued to function as heretofore and references to the work and findings recorded have been made under various headings in the preceding notes. During the year the following paper was published —

VASSALLO (S. M.) Duodenal Ulcer in Zanzibar — *East African Med. JI* 1937 Vol 14 No 3

Financial — Total expenditure on Medical Department Services amounted to £43,204 a sum which represents 9.7 per cent of the total revenue of the Protectorate.

SOMALILAND PROTECTORATE (1937)

Somaliland occupies the North-eastern horn of the African continent, jutting into the Indian Ocean on the south of the Gulf of Aden. The boundaries have been settled by agreements with France, Italy and Abyssinia. The chief ports are Berbera, Bulhar and Zeilah, and its area about 68 000 sq. miles, or one-sixth larger than England and Wales together.

Vital Statistics—The census figure for 1931 for all classes of the population is still used—a summary of the distribution by race reads: *Europeans and Whites* 68, *Natives (Somalis)* 344 700, *other natives of Africa* 458, *Arabs* 1 614, *Others* 543. As from the 1st July 1937 a praiseworthy experiment required tribal authorities to render monthly returns of births and deaths to District Officers. The first results of this departure are of interest:—

	Live Births	Stillbirths	Deaths
Berbera District	523	16	165
Hargeisa	450	—	210
Burao	14	—	—
Borama	633	9	140
Erigavo	19	7	33
Zeilah	159	19	87

Population figures for these districts are not included.

European Officials resident numbered 63, with an average number resident of 39; one was invalided home on sick leave before completing a tour of service, but no deaths were recorded. *Asiatic Officials* resident numbered 80, with an average number resident of 65; here again one was invalided home on sick leave before completion of a tour.

The vital records for Troops and Police for 1937 were as follows:—

Item	Number on Strength	Average Strength	Invalidings	Deaths
Troops (K.A.R.)	602	375	5	3
Police	654	624	17	2

Maternity and Child Welfare Work.—Nothing new recorded (see this Bulletin 1938 Supp. p. 87*) beyond the recommendation that a maternity and child welfare centre should be established (see *Public Health* below).

School Hygiene.—The position remains unchanged (see this Bulletin 1938 Supp. p. 87*).

Public Health Sanitation etc.—Dr J. C. R. BUCHANAN, Senior Medical Officer, was transferred for service with the Aden Government early in October, and no new appointment to the post of Senior Medical Officer was made during the year, though subsequently Dr P. S. BELL was appointed to the vacant post. In one section of the Report under review the aim of the Medical Department is questioned and the view is

expressed that the confidence of the native inhabitants has not yet been established. These views provoked a sharp reply from His Excellency the Governor who finally concludes "The Report reflects the greatest credit on the Senior Medical Officer and his staff and all concerned are to be congratulated upon the work which they have accomplished" (Dr Buchanan in an earlier Report refers to the difficulties met with in Somaliland (see this *Bulletin* 1938, Supp. p 88*))]

The references to general measures of sanitation are meagre. 15 *pit latrines* were constructed at Hargeisa and others are to be built in the same area. For other information the reader is referred to previous issues of this Supplement. In November a Standing Committee on Town Planning in Berbera was set up—the first meeting was held in December but no information is supplied of the results of this meeting or what schemes of work are envisaged by this Committee. Another Committee was appointed at the beginning of the year to survey human nutrition in the Protectorate. A Report was issued in February and recommendations included (a) That a system of milk distribution should be organized making supplies available for coastal areas (b) the establishment of a Maternity and Child Welfare Centre and (c) the establishment of a Central Laboratory. In May a Standing Committee was appointed on Human Nutrition "to co-ordinate and inspire the Government on this important matter".

Recommendations for future work envisage the establishment of a true Sanitary Service in the Protectorate latrines for the use of officers native servants in Berbera, and grading, re-surfacing and draining of the streets in the Town.

Five Appendices to the Report under review reproduce Ordinances and Notices enacted during the year in the interests of Public Health.

Hospitals Dispensaries etc—An addition to the list of Institutions providing for the treatment of patients is seen in the Abyssinian Refugee Camp Hospital established at Manjesh. The following statement summarizes the volume of work dealt with at all Hospitals during the year—

Hospital	In patients	Hospital Deaths	Out-patients
Berbera	786	22	9,332
Borama	702	18	4,837
Borao	620	18	8,628
Erigavo	98	6	3,813
Hargeisa	847	18	7,317
Spelsh	88	2	2,494
Zelsh	81	1	3,928
Manjesh (Aug-Dec)	289	12	5,200
Totals	3,601	92	45,445

It will be seen that even though an additional Hospital was functioning from August to the end of the year the numbers of in-patients and out-patients treated are fewer than those recorded during the previous year. This decline in treatments forms the

subject of special comment by the Senior Medical Officer who is of the opinion that the reason may be attributed to a reluctance on the part of natives to pay the small charges imposed for in-patient treatment (see this *Bulletin* 1938 Supp p 88*) and a belief that these charges apply to out patient treatments also (see also *Public Health* above) His Excellency the Governor does not subscribe to this opinion and points out that should a Somali who had lived at the expense of Government meet his death by accident much money would readily be found by his tribe to file and prosecute a claim for *dia* (blood money)

Having regard to the observations of the Senior Medical Officer the recorded figures for this or that disease can scarcely measure real incidence with any degree of accuracy. For example it is stated

A remarkable fall has occurred in the total number of cases of communicable disease treated by comparison with records for the previous three years.

Cases of *malaria* are said to have numbered 415 (see below) The fall in numbers cannot be attributed to failure of the rains for the rainfall figures are if anything higher than in previous years and it is added an immensely greater number of cases occurs than is recorded, the numbers shown merely representing those cases occurring in the neighbourhood of Hospitals or seen by Medical Officers on tour (see this *Bulletin* 1938 Supp p 88*) The incidence of the disease varies markedly in different parts of the Protectorate. On the coastal plain locally infected cases are almost unknown and the mosquito population is very small but in the south-eastern and south western parts of the country where rainfall is heavier the disease is liable to occur in widespread epidemics. Preventive measures of any value in these areas are at present impossible. During the year the direct sale of quinine to the native population at cost price was started but only 64 phials were sold. According to the classified Returns there were 319 in-patient and 415 out patient cases of malaria dealt with during the year. [Does this mean that 319 of a total of 415 cases first seen as out patients were subsequently admitted to Hospitals?] The distribution of types of infection among the 415 cases was *sub-tertian* 292 *benign tertian* 60 *quartan* 48 *cachexia* 14 and one unclassified case. At the Laboratory where 2965 blood films were examined, 179 were positive with *P falciparum* 91 *P vivax* and 62 *P malariae*.

One case of *smallpox* was reported from Hargeisa. It is believed the infection was introduced from Abyssinia. Active measures of vaccination were enforced in all areas, 3684 vaccinations were performed and no further cases occurred.

The measures taken at Burao for the removal of the town haafa to a new site and for the closure and destruction of certain coffee shops in the Camel Corps Lines appear to have been successful in bringing about a reduction in the numbers of cases of *relapsing fever*. In the whole Protectorate 488 cases were reported and of these 273 occurred in Burao (where in 1936 there were 618 cases).

A noticeable increase in the case incidence of *cerebrospinal fever* is recorded. Of the 16 cases dealt with 11 occurred in Hargeisa. In view of the suspicion that cases were being concealed, special Rules were issued empowering Medical Officers to enter premises examine

persons remove cases to Hospital, disinfect premises, etc. [These Rules are reproduced in detail in an Appendix and cited as The Contagious Diseases (Epidemic Cerebro-Spinal Meningitis) Rules, 1937.]

Six cases of *enteric fever* were diagnosed four of typhoid at Berbera and two (one each typhoid and paratyphoid) at Hargeisa. Of the 15 cases of *dysentery* recorded in the classified returns one was bacillary and for the remainder the type of infection was not determined. The returns also show that 677 cases of *enteritis* and 8318 of *constipation* were treated during the year (see this *Bulletin* 1938 Supp. p. 89.)

As regards *tuberculosis* 9 in-patient and 134 (in another place given as 143) out-patient cases of *pulmonary tuberculosis* were treated, and 60 in-patient and 131 out-patient cases of other forms of the disease. Other respiratory affections included the following —

	In-patients.	Deaths.	Out-patients.
Broncho-pneumonia	17	3	75
Lobar pneumonia	85	12	99
Bronchitis (all forms)	32	0	712

Eye diseases are a serious cause of disability. Hospital Returns show that 4,224 persons were treated for various eye affections and among the total were 3,325 cases of *conjunctivitis* and 149 of *trachoma*. For the latter condition 127 patients were treated at Hargeisa alone and the Report observes "The number of persons in the country actually infected must be of serious proportions."

Helminthiasis — A decline in the incidence of helminthic infections is noted and attributed to the cessation of the immigration of refugees from Abyssinia (see this *Bulletin* 1938, Supp. p. 89*). Only 140 cases of tape-worm infestation were recorded during the year.

Venereal diseases — The Hospital Returns supply the following data of cases treated during the year —

Syphilis			Gonorrhoea	Soft Chancres
Primary 90	Secondary 109	Tertiary 171	184	4

The numbers of cases of *syphilis* have increased from 220 in 1934 to 491 in the year under review. While little change is noted in the numbers of primary infections for each of the years 1934-1937 the latter stages of the disease have shown steady increase. This is especially true of congenital forms of *syphilis*. Having regard to these increases it is curious to note that the Laboratory Report records only 8 specimens of serum tested during 1937.

Four out-patient cases of *yaws* were treated during the year.

Other ailments mentioned with numbers of cases treated include the following — *Influenza* 543 *whooping cough* 63 *measles* 29. The deficiency diseases include *beriberi* 11 cases, *scurvy* 6 and *rickets* 5 while *pernicious* and other *anaemias* were responsible for 124 cases. *Skin diseases* of all kinds accounted for 8,342 cases and of these 5,854 were cases of *ulcers*. Affections produced by *external causes* totalled 7,356 and of these 4,427 were due to injury caused by blows.

Scientific—The Laboratory Report records that 5,936 specimens were received and examined during the year of these 2,935 were blood films (see *Malaria* above) and 378 were specimens of sputum of which 140 were positive for *Myco tuberculosis*. Nasal smears numbered 1 695 and 1 612 of these were positive with *Myco leprae* while among 128 urethral and vaginal smears 116 were positive with *N gonorrhoeae*. Twenty three Widal tests were carried out 8 reacted positively with *Bact typhosum* and 5 with *Br melitensis*. One out of five specimens tested gave a positive *Sachs-Georgi* reaction.

Financial—Total expenditure on Medical Services during 1937 amounted to £11 011 a sum which represents 5·2 per cent of the total revenue or 5·3 per cent of the total expenditure of the Protectorate during the same year.

RHODESIA

NORTHERN RHODESIA (1937)

Northern Rhodesia lies north of the Zambesi River with Tanganyika Territory and the Belgian Congo to the north, Nyasaland and Portuguese East Africa on the east, Southern Rhodesia and South-West Africa on the south and Portuguese West Africa on the west. The area of the Territory is estimated at about 287,950 sq miles and divided for administrative purposes into nine Provinces.

Vital Statistics—The only recorded facts presented under this title relate to European births and deaths and to European and Native Officials (see in this connexion this *Bulletin* 1937 Supp p. 79* and 1938 Supp p. 81*).

European deaths totalled 115—those under 5 years (16 in number) are classified in eleven age-groups—eleven infant deaths were recorded and these related to the 298 births registered give an *infant mortality rate* of 37·2 per 1,000 births. Total deaths are also classified by sex and cause of death, the latter according to a list of 38 titles.

European Officials resident numbered 616 with an average number resident of 517—three invalidings and four deaths were recorded. Of *Native Officials* 2,796 were resident, with an average number resident of 2,685—among this group 24 were invalided and 10 died.

Maternity and Child Welfare Work—At the European Hospitals, where 204 women were treated for *diseases of the puerperal state* 140 were cases of normal labour (138 admitted during 1937) while at Native Hospitals the corresponding numbers were 149 and 100 respectively.

The four *Welfare Clinics* (see this *Bulletin* 1936 Supp p. 73*) continued to function as usual—no details of the work dealt with at these centres are supplied. During the year arrangements were made for great increase in welfare work in the copper-belt. Each of three big copper mining concerns undertook to employ a Welfare Sister for work among dependants of employees, while Government undertook to employ a Welfare Sister for work among natives in each of the public township locations adjoining mine townships. This means the employment of six Welfare Sisters in the copper-belt. It is anticipated that similar activities will be started in Broken Hill.

School Hygiene—All European schools and scholars were inspected twice during the year by Government Medical Officers—evidence of poor nutrition was again reported. The usual dental inspections were made—here again attention is drawn to the fact that some parents fail to have their children's dental defects remedied, while others even refuse to allow their children to undergo dental examination (see this *Bulletin* 1938 Supp p. 82*). No results of the above inspections are supplied.

In all schools European and Native lessons in hygiene are given this subject receives special attention in the Jeanes School during the course of training of prospective teachers and their wives.

Public Health Sanitation etc—Dr J. F. C. HASLAM, Director of Medical Services, again refers to the impossibility of having a review of the public health of Northern Rhodesia upon reliable statistics, for such data are not available. With the co-operation and help of

administrative officers the Department is able to maintain reasonably close touch with the life of the Protectorate and to report no unusual morbidity or mortality incidence due to disease no widespread epidemic of serious or mild communicable disease nor food shortage amounting to or even approaching famine conditions. Improving revenue permitted the addition to the establishment of two medical officers and two nursing sisters yet despite these welcome additions the preventive staff remained as exiguous as ever—with only three health inspectors for the whole Protectorate plus two employed by local authorities. Recommendations have been submitted to Government with regard to the staffing of the Medical Department in relation to the medical and public health needs of the Territory. [The *Report of the Pim Commission 1938* states that the present medical provision for the native population is entirely inadequate (p. 290).]

With regard to *anti-malarial work* it is said that the drainage work at Lusaka was consolidated and improved with beneficial results (see this *Bulletin 1938 Supp.* p. 94*). Towards the end of the year a conference was convened of representatives of various parties interested in malaria prevention in Livingstone and neighbourhood and presided over by the Director of Medical Services. Proposals endorsed by representatives of Government the Livingstone Municipal Council Rhodesia Railways and the Zambesi Saw Mills at this conference provide for joint financing of work and ensure that for the future money will be available for anti malaria work in Livingstone to be carried out under the direction of the Medical Officer of Health and a Government Health Inspector.

Throughout most of the Protectorate where there is any organized system the pail system of *sewage disposal* is adopted. The system works satisfactorily in European quarters but in native locations pail closets are said to be seldom if ever other than grossly insanitary. The Lusaka *water supply* continues to be satisfactory as to quality and quantity storage capacity is said to be inadequate.

Organized recruiting of *labour* for employment outside Northern Rhodesia again increased and the voluntary exodus of individuals from the Protectorate is said to reach a very high total. In some cases the conditions under which recruited labour was being handled were unsatisfactory and called for the intervention of the Medical Department to compel offenders to comply with official requirements. On the other hand the conditions under which labour is employed at the copper mines are described as very good satisfactory arrangements are made for the housing rationing medical facilities etc. of employees while the care of and interest in the dependants of employees is receiving increasing attention (see also under *Maternity Work* above). Improvements have been made though more are required in respect of medical care and sanitary arrangements of the thousands of labourers employed by the Zambesi Saw Mills but the conditions under which agricultural labour is employed are not altogether satisfactory.

There is much room for *housing improvement* in the larger town locations along the railway. Dr Haslam opines that a necessary preliminary step is to decide in principle (a) who is responsible for the housing of Africans within or in connexion with European townships and (b) who is to be housed in township locations. These questions are discussed at some length.

In the principal centres of European population reasonable adequate *inspection and control of food for sale* is provided, but the posting of a whole-time Medical Officer of Health in Livingstone soon showed there is still much room for improvement. *Milk supplies* are nowhere to be regarded as safe without boiling or pasteurization. The Committee appointed to study various aspects of diet and nutrition (see this *Bulletin* 1938 Supp. p. 93) has submitted a report which has since been printed.

The *creation of the statutory Native Authorities* in hygiene and sanitation is being cultivated and stimulated by District Officers with success. *courses of instruction* given to Chiefs at the Jeanes School are listened to with interest and results are seen in more cleanly and orderly villages.

Training of Health Department Personnel—The first course of Training of Medical Orderlies at the Native Medical Training School at Lusaka ended in September 1937 (see this *Bulletin* 1938 Supp., p. 93). In the light of experience gained it was decided to extend the next course to two years. There is considerable opportunity for the employment of native girls trained in nursing duties, etc. but progress in this direction is limited by the small number of girls of prescribed standards of education. *Abereshi Mission* of the London Missionary Society has for two years received financial aid from Government for training girls in medical work, but the results have so far been negligible.

Port Health Work—Arrangements remain as previously described (see this *Bulletin* 1937 Supp. p. 81) and nothing of unusual interest was recorded during the year under review. As regards *aerial traffic* the airports at Lusaka and Livingstone possess all the requirements of a "sanitary aerodrome" but Mpika (where aircraft from the north first land in Northern Rhodesia) has not even the requirements of an "authorized aerodrome." It is understood that aircraft arriving from the north are to make their first landing at Kasama airport which conforms to the requirements of an "authorized aerodrome."

Hospitals Dispensaries etc—No change is recorded in the numbers of European and Native Hospitals maintained by Government (see this *Bulletin* 1937 Supp. p. 81*) but during the year information was received that the Colonial Development Fund would contribute half the capital cost for the erection of a Native Medical Training School, Native Hospitals at Lusaka, Abercorn and Fort Jameson and 22 small Rural Hospitals and Dispensaries. Tentative provision was made in the 1938 Estimates for these additions.

Government maintained 29 *rural dispensaries* staffed by Africans, some of these dispensaries accommodate a few in-patients. Supervision of these centres remains unchanged (see this *Bulletin* 1937 Supp. p. 81) but steps are being taken to ensure increased supervision and control.

There are approximately 30 *Mission Hospitals and Dispensaries* in the Protectorate and even a larger number of mission stations where some sort of medical aid for natives is available.

The *Copper Mining Companies* continue to maintain admirable staffed and equipped hospitals for European and Native employees and their dependants.

The morbidity and mortality experience of the Protectorate in 1937 as reflected in the classified returns of Hospital in-patients can be summarized as follows —

Institution	In patients			Out patients
	Admitted	Treated	Died	
<i>Government Hospitals —</i>				
7 European	1 731	1 763	42	'
12 Native	11 344	11 922	415	41 494
28 Dispensaries	No details			
30 Mission Hospitals	No details			
4 Mining Companies	11,374	'	218	'

The steady increase in the numbers of native in patients is held to indicate increasing confidence in European medical treatment while the diminishing mortality each year among such patients suggests they are inclined to seek medical assistance more promptly than was their custom in the past.

As regards the European population it may be added that approximately 7,500 (out of a total in the Protectorate of 14 000) reside in the Copper-belt and receive medical treatment from Mine Medical Staffs and in Mine Hospitals. The Chief Medical Officer Rhokana Corporation reports that among some thousands of employees the crude mortality rate in 1937 was only 6·4 per 1 000.

The following notes summarize the observations in the Report under review concerning morbidity experience reported from twelve medical districts during 1937.

Malaria continues to be the chief cause of invaliding among Europeans and with *blackwater fever* the commonest cause of death. During the year 538 European cases of malaria were treated in hospitals (528 admissions) with one death, and 12 cases of *blackwater fever* with 7 deaths. All the malaria cases were *subtertian* infections and the vector practically always *A funestus* or *A gambiae*. Total deaths among Europeans in the Protectorate due to malaria were eight and to blackwater fever eleven.

Among *natives* the disease takes a more chronic and permanent form. 897 in-patient cases were treated with 19 deaths.

The only *filaria* infection known to occur is by *A perstans* and the embryo is frequently seen in films examined for the presence of other parasites. Dr Haslam reports positive findings in one third of 37 films examined in the Luangwa Valley.

Early in the year *bubonic plague* was reported from the Balovale District of Barotseland. the diagnosis of 9 cases and 3 deaths was confirmed. Over 40 000 rats were accounted for in the subsequent campaign. Almost simultaneously with this outbreak came reports of plague or something like it in the South of the Territory. A Medical Officer toured the area but no evidence of a fatal enzootic among rodents was found nor could any confirmation of a human case be discovered.

Of *cerebrospinal meningitis* 18 cases with 8 deaths were reported, 12 of the cases and 6 of the deaths occurring among natives. Twenty seven non fatal cases of *alacrim* and 28 cases of *influenza* with 7 deaths were recorded. all these were in natives. These figures are taken

from the returns of notified cases of infectious diseases but in another place it is stated that epidemics of influenza were reported from Balovale Broken Hill, Choma and Fort Jameson—places widely separated. At Broken Hill native adult males were specially affected, 171 cases being recorded.

Scarlet fever is uncommon in the tropics but two small epidemics occurred at Choma and Broken Hill. 21 non-fatal cases among European children were notified. Of *measles* 22 non-fatal cases among Europeans, and 121 with 4 deaths among natives were reported. There were also 12 cases of *whooping cough* among Europeans and 134 among natives and 76 non-fatal cases of *chickenpox* among Europeans and 213 cases with 18 deaths among natives.

Notified cases of *relapsing fever* were, Europeans 2. Natives 88. One European case and 50 native cases were treated at Fort Jameson. The tick *O. morsitans* is common in all parts of the country but relapsing fever due to tick-borne *S. duttoni* is not common.

Typhoid fever was responsible for 6 European and 15 Native cases with one European and two native deaths. Of *dysentery* 164 cases were notified with 8 deaths. Eleven of the cases occurred amongst Europeans, 9 being amoebic and 2 bacillary infections. All were non-fatal. The 153 cases among natives were distributed as to 44 amoebic, 12 bacillary and 97 undefined.

Thirty-four cases of *sleeping sickness* were notified with 8 deaths. Not a single clinical case of the disease was discovered during the course of a 180-mile tour across the Luangwa Valley nor was news of any case obtainable. 37 blood films were examined, all were negative for trypanosomes.

Concern is felt regarding *tuberculosis*. Cases are not reported in large numbers but are seen at medical stations sufficiently often to give rise to disquiet. Six European and 63 native cases were notified during the year and all but 5 (among natives) were of the *pulmonary* form of the disease which caused the deaths of 2 Europeans and 19 natives. *Pneumonia* continues to be a chief cause of death among natives. Among 412 cases (other than influenza pneumonia of which there were 33 cases and 10 deaths) of natives treated in hospitals 93 patients died. The case mortality appears to have been unusually high in Broken Hill, where among 50 cases 21 deaths occurred.

Chief interest regarding *helminthic diseases* is said to centre round *bilharzia*. Knowledge of its incidence and distribution are far from complete but each year it seems clearer that (a) the infection is much more common than has been realized, (b) that infection is frequently present without giving rise to symptoms of disability and (c) that present text-book descriptions give a very incomplete picture of the disease and might lead to cases being overlooked. Microscopic examinations of every native case admitted to hospital at Broken Hill and Choma showed that upwards of 20 per cent. were infected with either *S. haematobium* or *S. mansoni*; and that the majority exhibited no symptoms ordinarily associated with schistosomiasis. Similar findings were recorded in other areas. Hospital Returns show that 328 in-patient cases of schistosomiasis were treated and that 7 deaths were ascribed to this cause.

Infestation by *hookworm* is common among the native population. 454 in-patient cases were treated. Available knowledge is insufficient

to determine with accuracy to what extent hookworm infestation is of economic importance in various areas of the Territory. In the copper mines precautions are well and thoroughly applied.

Ascari infestation is common almost everywhere and in the Bangweulu swamps is believed to be nearly universal.

Veneral Diseases—Syphilis is said to be all too common everywhere and in some areas affects a very large proportion of the native population (see this *Bulletin* 1938 Supp. p. 95*). Hospital Returns supply the following figures relating to native in-patients—*Syphilis* 2 460 cases 18 deaths *gonorrhoea* 247 cases and *granuloma venereum* 3 cases. Among Europeans one case of *gonorrhoea* was reported.

The Zambesi Valley provides most of the cases of *yaws* but a new focus of infection not previously reported has been notified in Hasama Lwela's country in the Fort Rosebery district. Native in-patient cases numbered 376.

Among other diseases noted in the Report the following call for brief mention. Notified cases of *leprosy* numbered 107 all were natives. The Medical Officer Fort Rosebery has previously reported round-celled sarcoma and epithelioma in natives he now reports true carcinoma of the stomach large intestine and prostate. *Conjunctivitis* is specially referred to in reports from three districts in Mongu 336 native cases were treated and severe complications were seen. *Scabies* is widespread, 630 natives were treated as in-patients while 452 patients were treated for *tropical ulcers*. Cases of extensive burning with a history of a fall into the fire during a fit are frequently met with in native hospitals and the fit often assumed to be epileptic. It is doubted whether epilepsy is so greatly the monopoly of the people in the areas showing the largest numbers of these cases it is suggested that some may be due to cysticercus of the brain or to temporary loss of consciousness due to addiction to *dagga*.

Scientific—Routine examination work continues along lines previously described (see this *Bulletin* 1938 Supp. p. 95*) and during the year 4 424 specimens were examined.

Recommendations regarding laboratory facilities were made to Government and copies were embodied in a Memorandum prepared for the Pim Commission.

[The Report of the Pim Commission 1938 observes: The Territory is still entirely without laboratory facilities and the Director is anxious to remedy this defect. p. 293.]

Financial—Expenditure on Medical Department Services during 1937 amounted to £67 924 a sum which represents 6.9 per cent. of the total revenue or 7.5 per cent. of the total expenditure of the Protectorate during the same period.

SOUTH AFRICA

BASUTOLAND (1937)

Basutoland forms an irregular oval within the Union of South Africa, the main axis, about 150 miles long, lying in a north-easterly direction. The Orange Free State Province Natal and the Cape Province form its boundaries. It is mainly mountainous, and has an area of 11 716 sq miles, or nearly that of Belgium. The High Commissioner for South Africa is Governor of Basutoland.

Vital Statistics—The population figures resulting from the Census taken in 1936 are presented (see this *Bulletin* 1938 Supp. p. 96*) and record 1 434 Europeans 660 650 *Bantu* and 1 600 coloured persons (other than *Bantu*). Births marriages and deaths are not registered for any section of the native population.

European Officials resident numbered 135 two died but no invalidings were recorded during the year.

Public Health Sanitation etc—During the year under review Dr H. W. DYKE, Principal Medical Officer paid periodic visits to all Government Medical Stations with the exception of Makhotlong. Reference is made to the improved methods of sewage disposal introduced at Leribe and Moshale's Hoek Government Reserves (see this *Bulletin* 1938 Supp. p. 96*) a year ago. It is also explained that the construction of bore-hole latrines in Basutoland is impracticable for villages are usually sited on hills where rocks and gravel are so near the surface that augers would fail to penetrate. The villages are usually small and the dry atmosphere and strong sunlight combine to bring about the rapid disintegration of excreta the system is by no means ideal for it results in a number of fly-borne and water-borne diseases yet it is not deemed advisable to disturb existing conditions but to defer action until the people at large have developed a more sanitary outlook. The difficulties encountered when attempts are made to control the breeding of house-flies in a country like Basutoland where horses and cattle are numerous are discussed. It is said that "Baber" traps erected at the Police Stables Maseru, had the effect of reducing the incidence of flies by 75 per cent. The cost of these traps prohibit their adoption for universal use.

Previous Reports have referred to unprotected water supplies (see this *Bulletin* 1938 Supp. p. 96*). A survey of village sources of supply showed that conditions were worse than had been realized and improvements are urgently needed in the interests of public health. A scheme has been inaugurated by Government for the protection of village springs from surface pollution so far 80 springs have been dealt with and by 1939 it is expected that work on 400 springs will have been completed. The drying up of supplies in some areas may necessitate the construction of bore-holes and the pumping of water from underground sources.

The question of *native diets* is discussed at some length. It is interesting to note that stimulated by the Agricultural Department, a notable increase in the number of vegetable gardens is recorded, large numbers were entered for the competition conducted by the Department, and that the staple diet of maize is being progressively

improved by the addition of legumes and vegetables. Bulls of milk producing strain have been purchased and efforts are being made to encourage the breeding of Swiss goats of high-grade milking properties and the combined effects of these admirable undertakings should be reflected in the improved condition of the children in the country. Though the Soya bean and similar plants with a high vegetable fat content cannot be grown in Basutoland by reason of uncertain spring rainfall and autumn frosts the Agricultural Department is experimenting with a view to producing crops rich in vegetable fats suited to the normal climatic conditions of the country.

Hospitals Dispensaries etc—Medical facilities for the native population have so far been supplied almost entirely by Government. Private practice in the territory has not been sufficiently remunerative to attract either European or Native doctors with the result that for all practical purposes there is but one doctor per 50 000 inhabitants. This disproportion will shortly be relieved by the establishment of three *Medical Missions*. Dr Dyke explains that large sections of the highland population have to make long journeys over dangerous mountain tracks to obtain medical aid with the result that cases of acute illness or confinements are not able to receive adequate attention. Approach to these remote areas by aeroplane is impossible owing to the lack of suitable landing grounds properly staffed and equipped. *Medical Missions* subsidized by Government appear to be the only solution to this problem.

There are now eight Government Hospitals established in different parts of the territory with bed accommodation for 172 natives and 13 Europeans (see this *Bulletin* 1938 Supp p 96*). Additions to these hospitals provided increased bed accommodation and the hospital at Mofhotlong was completed and brought into use during the year. Various improvements have been carried out to hospitals and dispensaries.

In-patients admitted to all Hospitals numbered 3,527 and the total treated 3 644 with 225 deaths.

Of *out-patients* treated at the eight *Government Dispensaries* there were 72 264 new cases and 38,543 subsequent attendances for treatment were recorded.

The increase in the number of new cases and attendances of out-patients is ascribed to increased prosperity which enables patients to pay the small fee charged for treatment and also to the greater confidence in Government Medical Officers the native witch doctor and herbalist are gradually being superseded (see also *Scientific* below).

The training of female African nurses which commenced in 1936 (see this *Bulletin* 1938 Supp p 97*) has proved highly successful. All first year probationers passed the examination with a high standard of efficiency and have commenced their second year course of training. Six new probationers have been selected to commence the course in 1938.

In previous issues of this *Supplement* reference has been made to the fortunate freedom from certain tropical and sub-tropical diseases which characterizes usual morbidity experience in Basutoland. The notes which follow briefly summarize the references in the Report under review to the incidence of the more important communicable and general diseases in 1937.

No case of human plague was reported during the year. Poisoned wheat continues to be regularly distributed by Government to the native population, and where systematic surveys show evidence of gerbilles breeding up the Chiefs and Headmen are advised to speed up their destruction by means of the poisoned wheat (see also this Bulletin 1938, Supp. p. 87*).

The incidence of typhus fever was the lowest so far recorded with 18 cases and 3 deaths. The decline in incidence may be ascribed to a variety of factors—the disease may be losing some of its virulence. Basutos are better nourished than at the time of the disastrous epidemic of 1933-34 (see this Bulletin 1938 Supp. p. 79* and 1937 Supp. p. 86*) and widespread immunity has been acquired by survivors. Still further it may be noted that the special methods adopted in 1935 for dealing promptly with any outbreak have proved conspicuously successful for example an outbreak occurred at a remote mountain village with 5 cases, but energetic action prevented the occurrence of further cases. Dr Dyke describes in detail the system of de-vermining carried out (see this Bulletin 1937 Supp. p. 86* and 1938 Supp. p. 87*).

It is said that 255 cases of typhoid and paratyphoid fever were reported during the year but according to classified returns there were 98 in-patient cases with 15 deaths and 237 cases among out patients. Among in-patients 82 of the cases were Bact. typhosum infections, on Bact. paratyphosum A and in 13 cases the type of infection was not defined among out-patients 225 were typhoid and 12 unclassified. In many cases the source of infection is said to be traceable to polluted water supplies. The improvements now being carried out (see Public Health above) should result in reducing the incidence of the disease. Dysentery is not mentioned in the text of the Report but 39 in-patient cases (5 deaths) and 216 out-patient cases are recorded. Among in-patients 2 were amoebic and 12 bacillary infections but in the remaining 24 cases the type of infection was not determined. The out-patient cases comprised 149 undefined as to type, 28 bacillary and 39 amoebic infections. Under the title diarrhoea and enteritis appear 1 432 cases under 2 years and 1 429 at ages two years and over.

Tuberculosis.—In-patients treated for the disease totalled 107 (18 deaths) and of these 40 were cases of the pulmonary type of the disease with 11 deaths at the dispensaries where 832 cases were dealt with 443 were of the pulmonary type. It is said that pulmonary tuberculosis has very appreciably diminished since 1935. The effects of prosperity and of good food supplies on diminishing the incidence of prosperity are commented upon (from 1935 crops were good and money earned by labourers plentiful) and it is opined that good economic conditions plus the efforts being made to improve dietaries (see above Public Health) should bring about further improvement in the incidence of the disease among the Basuto. Other respiratory diseases mentioned in the Report include 5 323 cases of bronchitis and 185 cases of pneumonia of the latter 120 cases received treatment as in patients and 24 died.

Unbalanced diets have been the subject of brief mention in the section Public Health above. It remains to say that the effects are reflected in the occurrence of 120 cases of scurvy and 270 cases of pellagra while

the 4,432 cases of *dyspepsia* and 6,221 cases of *constipation* recorded are largely attributed to imperfectly balanced diets.

We have already referred to the fact that in previous Reports reference has been made to the freedom from certain tropical and sub-tropical diseases characterizing morbidity experiences in Basutoland, and attention has been called to the comparative absence of *helminthic diseases*. The classified returns show only 212 cases of *diseases due to internal parasites* among them being 100 cases of *tuberculosis*.

Leprosy—In an Appendix to the Report under review the Superintendent of the Leper Settlement describes the year's work in detail while in another Appendix Dr R. C. GERMOND Medical Officer of the Leper Settlement reports the results of a survey of a portion of the Mafeteng District. To the Leper Settlement 104 new cases were admitted during the year 27 recurrences and 27 re-admitted deserters. There were 59 deaths 71 patients were discharged 41 deserted and at the end of the year there remained 669 patients under treatment. The Report discusses the work under such headings as (a) origin of new cases admitted (b) duration of disease before admission (c) age distribution (d) treatment etc.

The results of Dr Germond's survey are encouraging and tend to show that the incidence of the disease is lower in the Lowlands area than in the surveyed part of the Eastern Highlands for out of a population of 15,000 persons only 7 cases were discovered, and of these one was spontaneously arrested and in two the diagnosis was not confirmed (see also this *Bulletin* 1938 Supp. p. 98*).

Venereal diseases—The following data have been extracted from Hospital and Dispensary Returns and indicate the numbers of cases treated during the year—

Item	In patients	Out-patients
Syphilis	11	9,630
Gonorrhoea	10	1,651
Granuloma venereum	—	5
Soft chancre	—	31

It is observed that though the increase in the numbers of cases dealt with may be attributed in part to the increased confidence of the natives in modern medicine greater incidence of primary and secondary stage cases indicates the occurrence of an undue number of new infections. Dr Dyke explains that economic conditions and food supplies are closely correlated with syphilis incidence. When conditions are good an abundance of kaffir beer is brewed by infected native women at points of entry to the territory used by natives returning from the Mines. These men spend their earnings at these places become infected, and carry this infection to their native villages and infect their own women-folk. The latter do not seek treatment until the secondary stage has well developed meanwhile they may be infecting their own or neighbouring children through the handling of household utensils. At the Leribe and Mophale's Hoek dispensaries enquiries were made of 1,500 consecutive out patients as to whether or not they had had or still had syphilis. At Leribe 55 per cent. and Mophale's Hoek 31 per cent. admitted infection.

Among other diseases recorded in the Report appear 1,580 cases of influenza 1,332 of whooping cough 3,541 of rheumatism 1,791 of diseases of the skin

Scientific—In the absence of a Laboratory Report two special reports included as Appendices to the Annual Report under review call for mention. The first of these contributed by Dr. R. Germond describing a special leprosy survey and the results obtained, has been referred to in the section *Leprosy* above. The second, furnished by Dr. A. E. Young Medical Officer Maseru, deals with the surgical treatment of urinary fistula among Basuto women a condition commonly met with and usually the result of unskilled native assistance in childbirth. During the two years 1836-1837 eighteen cases were treated by implantation, and 16 were discharged as cured. Operative methods anaesthesia and end results are described. In the words of the Principal Medical Officer "The success achieved in this operation on Basuto women by the Medical Officers at Maseru and Leribe will compare favourably with that obtained by surgeons of high repute in the medical world."

Financial—Total expenditure on Medical Department services during 1837 amounted to £47,540 the Lepet Settlement accounting for £17,926 of this sum

BECHUANALAND PROTECTORATE (1837)

Bechuanaland is bounded on the south and east by the Union of South Africa, on the north by Southern Rhodesia, and on the west by South-West Africa. It has an area of about 275,000 sq miles. The High Commissioner for South Africa supervises the affairs of the Protectorate

The Annual Medical Report for the year 1837 had not been received at the time of going to press on October 16th 1839

SWAZILAND (1837)

The Swaziland Protectorate is situated in British South Africa, between the Drakensburg and Lebombo Mountains and is bounded on the north, west and south by the Transvaal, and on the east by Portuguese East Africa and Zululand. Its total area is 6,705 sq miles.

Total Statistics—A census taken in 1838 returned the general Native population as 153,770 other population figures supplied are European population 2,740 and Coloured population 705 making a grand total of 157,215

Registration is not compulsory and no birth, death, or infant mortality data are available

European Officials resident number 106 with an average number resident of 101. No deaths were recorded but one Officer was invalided during the year. Resident Native Officials numbered 162 with an average number resident of 158. No invalidings or deaths were recorded. The health of both European and Native Officials was good throughout the year

Maternity and Child Welfare Work—The Raleigh Fitkin Memorial Hospital remains the only institution in the territory where a special department under the charge of a British Red Cross Society Nurse deals with this important branch of public health work. The volume of work dealt with included Nursing Mothers examined 1 807 deliveries 180 ante natal examinations 2 212. At all hospitals in the Protectorate 245 cases of normal labour were dealt with.

Ante natal work is carried out and Child Welfare Clinics are conducted at all Government hospitals and Medical Outposts as part of the ordinary routine of work, though no details are supplied it is reported that attendances are increasing.

School Hygiene—The health of European children in the highlands of the country was good but many of those resident in the bush veldt suffered from malaria during the autumn. The prevalence of dental caries is again a subject of comment. There is no resident dentist in the territory. It is intended that nurses in charge of Medical Outposts shall give elementary instruction in hygiene in the schools in their areas whenever possible.

Public Health Sanitation etc—Dr D DREW the newly appointed Principal Medical Officer submits the Annual Report for 1937 though he was not serving in any part of the Protectorate during the year under review. Beyond the fact that during the autumn a severe epidemic of malaria occurred it is said the general health of the territory was satisfactory during the year under review. In the absence of further information it is presumed that methods of *scavage and refuse disposal* remain unchanged (see this *Bulletin* 1937 Supp p 93* and 1938 Supp p 104*). With the exception of Bremersdorp *water supplies* of all townships are described as unsatisfactory. Proposals are under consideration for the improvement of supplies in Mbabane Goedgedun and Stega.

The largest number of *native labourers* is employed by an Asbestos Mining Company. A Government Medical Officer has visited the mine regularly and attended to the needs of employees but the Mining Company will shortly employ a whole-time Medical Officer of their own. The health of natives employed in the alluvial tin mines continues to be satisfactory.

Training of Sanitary Personnel—Under this heading it is reported that the appointment of a Sanitary Inspector has been authorized. This Officer will undertake the training of native sanitary inspectors who will be posted to suitable centres throughout the Protectorate. It is said that the sanitary arrangements in the eight townships leave much to be desired. The work of the Town Inspectors is fully appreciated but untrained men cannot be expected to raise the sanitary services of communities to a satisfactory level.

Recommendations for future work emphasize the urgent need of providing adequate and satisfactory water supplies at Mbabane Hlatikulu and Goedgedun (see also this *Bulletin* 1938 Supp p 104*).

Hospitals Dispensaries etc—The increase in the numbers of patients treated at hospitals continues. The additional accommodation urgently needed at the Raleigh Fitkin Memorial Hospital will be met by extensions to existing buildings made possible by generous public subscriptions to commemorate the Silver Jubilee of King George V. To meet the inadequate accommodation at the Mbabane Hospital,

proposals are being submitted which should cope with probable requirements for the next few years. The extensions to the Hlatikulu hospital have more than justified themselves for even the additional accommodation provided was frequently overcrowded during 1937.

There are two *Government dispensaries* and a third is in course of construction, and there are also three *Mission dispensaries*. Another *Medical Outpost* was opened during the year bringing the total to six. At all these centres valuable work is being carried out.

At all hospitals in the Protectorate 3,278 in-patients were treated and 115 deaths were recorded. 1,571 in-patients were treated at the Raleigh Fitkin Memorial Hospital. The following figures relate to out patients treated at various centres during the year under review —

Tw. Government Hospitals	19,943
Two Government Dispensaries	7,530
Six Government Medical Outposts	6,584
Raleigh Fitkin (Mission) Hospital	16,577
Three Mission Dispensaries	12,843

The training of native nurses progresses satisfactorily at the Raleigh Fitkin Memorial Hospital. 4 nurses are in the first year of their training, 2 in the second, 2 in the third, and 4 are completing the final year of the course.

There is no institution in the Protectorate for the housing of *mental patients*, many of whom have to be accommodated in the gaols, and the more violent sent to institutions of the Union of South Africa. It is suggested that a central institution might be provided for the use of the three High Commissions Territories.

In the autumn of 1937 one of the worst epidemics of *malaria* was experienced. The disease was severe in type and contrary to usual experience in Swaziland, a number of cases of cerebral malaria were treated. No figures of case incidence are given for it is said the large majority of patients obtained quinine from the various quinine depots and treated themselves, and no record of numbers of people applying for quinine appears to have been maintained. In patients treated for the disease totalled 712 and 19 deaths were recorded. types of infection were *benign tertian* 686 *subtertian* 23 and *blackwater fever* 3 cases.

Although these infections are unmentioned in the text of the Report, Hospital Returns appear to show 11 cases of *smallpox*, 10 of *scarlet fever*, 22 of *whooping cough* and 74 of *influenza*. [We say "appear to show" for from the original typescript it is difficult to distinguish the precise position of some of the figures. It is noted also that the nomenclature used is that of the International List 1921 Revision: it is suggested that the special nomenclature for British Colonies might be adopted.]

Eighteen cases of *enteric fever* were treated in hospitals with 6 deaths. In the Southern District where cases are usually reported, prophylactic inoculation was carried out with the result that no case occurred in the area.

Fifty-nine patients were treated in hospitals for *dysentery* and 4 died. the types of infection were *amoebic* 48 *bacillary* 11. Amoebic infections are said to be relatively common in certain parts of the middle and low veldt, and many cases of chronic *diarrhoea* (54 in-patients treated) are said to be amoebic in origin.

All Medical Officers are said to be of the opinion that *tuberculosis* is increasing the most common manifestation being the *pulmonary* form of the disease. Of the 83 cases (all forms) treated in hospitals with 10 deaths 52 of the cases and 9 of the deaths were due to *pulmonary tuberculosis*. The problem is serious and not easily solved for in a country of meagre financial resources institutional treatment is scarcely feasible apart from the fact that difficulty would be experienced in persuading patients to remain in an institution long enough to effect complete cure. Efforts are being made to build up the resistance of natives to the infection by the improvement of local diets. Other *respiratory ailments* treated in hospitals included 61 cases of *pneumonia* with 10 deaths, and 45 non fatal cases of *bronchitis*.

The prevalence of *schistosomiasis* is again a subject of comment (see this *Bulletin* 1938 Supp p 106*) and it is said that bilharzia infections are probably responsible for more chronic ill health than is usually realized. Hospital Returns show that 30 in patients were treated for *taeniasis* and 62 for *schistosomiasis*.

Leprosy does not appear to be increasing only one case was reported during the year. Proposals have been submitted for the transfer of the present leper settlement to a more suitable site.

Veneral Diseases—Judging by admissions to hospitals and treatments at V D Clinics and Medical Outposts it is said *syphilis* appears to be increasing. The only figures presented are those for hospital in-patients 368 cases being recorded. As regards *gonorrhoea* the disease is said to be much more common than the 34 hospital cases indicate and it is probable that a large number of the women attending various centres for gynaecological conditions have been infected with the disease. Natives do not regard gonorrhoea as a serious ailment nor do they associate sterility and other diseases of women with this condition.

Financial—Total expenditure on Medical and Sanitary Services during 1937 amounted to £18 837 a sum which represents 15·7 per cent of the total revenue of the Protectorate during the same year.

SAINT HELENA (1937)

The Colony of St. Helena consists of the Island of St. Helena (47 sq miles in area) and its dependency the Island of Ascension (34 sq miles in area). St. Helena lies in the South Atlantic in lat. 15°55 S and long 50 42W and is about 4 210 miles from Plymouth and 1 700 miles from Cape Town. Ascension lies about 700 miles north west of St. Helena.

Vital Statistics—The estimated population for the year under review was 4 515 [in another section given as 4 415]. *Registered live births* numbered 132 and deaths 32, the resulting crude birth and death rates being 29·2 and 7·1 per 1 000 respectively. *Infant deaths* numbered 6 so the infant mortality rate was 45·4 per 1 000 live births. During the year 8 *stillbirths* were recorded.

The numbers of *European Officials* are not stated, but no deaths were recorded in this group though one official was invalided on grounds of *cancer* of the floor of the mouth.

Maternity and Child Welfare Work—With a view to raising the standards of maternity services in the Island a scheme was inaugurated in February for the training of selected women at the Civil Hospital over a period of six months to be followed by six months practical work with the best midwife on the Island. Two selected women completed their hospital training and following examination by the Senior Medical Officer are now engaged on the second six months of the course while two other women have commenced their training at the Hospital.

Up to the present no Child Welfare Work has been undertaken but the Secretary of State has approved a vote for this purpose and a clinic will be established at the Civil Hospital.

School Hygiene is not mentioned.

Public Health Sanitation etc—With the exception of an outbreak of influenza in the middle of the year the general health of the population was good throughout 1937.

Dr J GRAY Senior Medical Officer calls attention to economic conditions in the Island practically the only article of export is flax fibre and the development of that industry cannot keep pace with the needs of a steadily increasing population. The result is reflected in extreme poverty and what are described as appalling housing conditions. Much of Jamestown the capital is slum property and it is added some of this slum property belongs to Government. Instead of giving a lead by upkeeping the property the houses have in some instances fallen into wrack and ruin. In country districts conditions are equally objectionable with families living in a single room many houses in town and country should be condemned as unfit for human habitation, yet no other accommodation is available (see this *Bulletin* 1938, Supp p 108*). Once again Dr Gray emphasizes that Medical Officers should be gazetted Health Officers an up-to-date Health Ordinance should be introduced and trained Health Visitors should be appointed.

No reference is made to methods of *sewage disposal water supplies* etc. and in the absence of information it is presumed services remain as described in this *Bulletin* 1937 Supp p. 97*.

Port Health Work—No change in the system of services is recorded (see this *Bulletin* 1937 Supp p 97*). During the year 41 ships called at the Island.

Hospitals Dispensaries etc—Services and facilities remain as previously described (see this *Bulletin* 1937 Supp., p 98*). During the year 291 in-patient cases were dealt with and 13 Hospital deaths recorded. *Out-patient* attendances at the Civil Hospital numbered 5 083 and at the Hutts Gate and Sandy Bay Dispensaries 1 030 and 288 respectively. Medical Officers continue to hold outdoor dispensaries at their homes each morning and attendances at these totalled 1,907 while visits to patients in their own homes numbered 1 108.

The condition of the *Prison* and health of the inmates are said to have been satisfactory. Dr Gray's condemnation of the *Lunatic Asylum* is repeated (see this *Bulletin* 1938, Supp p 108*).

During the month of June an outbreak of *influenza* occurred. Hospital in-patients treated for the disease numbered 32 many of the cases were complicated by lobar pneumonia, but none terminated

fatally. Only one fatal case of *tuberculosis* (non respiratory) was recorded. Among the respiratory diseases, 14 patients were treated for *acute bronchitis* and 3 for *broncho-pneumonia* of *lobar pneumonia* there were 6 cases and one death.

Three non fatal cases of *amoebic dysentery* were recorded. (With regard to previous experience the reader is referred to this *Bulletin* 1937 Supp. p 98* and 1938 Supp. p 108*.)

The incidence of *beriberi* is said to be declining. 7 non fatal cases were dealt with during the year. *Diseases of the digestive system* were responsible for 21 hospital cases with one death.

Special attention is directed to the high incidence of *malignant disease* in the Island. During the year 5 in-patients received treatment and one died while an additional 4 deaths due to cancer occurred in the homes of patients and two cases left the Island. During the past 26 years 76 deaths have been ascribed to cancer.

There is one case of *leprosy* on the Island. the patient is segregated and treated with iodized moogrol but no improvement in condition can be recorded.

No case of *syphilis* was seen but 9 persons were under treatment for *gonorrhoea* and several for stricture of the urethra due to the same cause.

Financial—Expenditure on Medical and Sanitary services during 1937 amounted to £3 213 a sum which represents 7.7 per cent. of the total revenue of the Colony during the same year.

NORTH AFRICA

SUDAN (1937)

The Sudan is bounded on the north by Egypt, east by the Red Sea, Eritrea and Abyssinia, south by the Uganda Protectorate and Belgian Congo west by French Equatorial Africa. Its western and northern frontiers meet in the Libyan desert. The greatest length north to south is approximately 1,300 miles and from east to west 1,200 miles. Its total area is about 1 008 100 sq. miles.

Total Statistics—Estimated population figures are given for 8 of the 9 Provinces but complete vital statistical data are available for Khartoum Province only. As regards the Provincial population according to the 1937 estimates the populations of four Provinces have decreased in numbers, three have increased and in one the figure is unchanged, by comparison with 1936 data these changes are indicated in the Table below by the signs (+) (—) and (†) respectively [Why the population figure for the White Nile Province is omitted is not stated.]

Province	Estimated Population	Province	Estimated Population
Khartoum	255 166 (—)	Darfur	715,843 (—)
Northern	571,330 (+)	Upper Nile	502,163 (—)
Blue Nile	760 224 (—)	Equatoria	1 129 000 (+)
Kassala	419,857 (+)	White Nile	Not given.
Kordofan	1,222,729 (†)		

These figures lacking the population of the White Nile Province, give a total of 5,576 012 persons.

The data for Khartoum Province are *population* 255 166 *registered live births* 4,274 *registered deaths* 2,454 *and infant deaths* 345. The crude birth and death rates were 16.8 and 9.7 per 1 000 respectively and the infant mortality rate 80.7 per 1 000 live births. For Khartoum Province births are classified by sex and nationality and deaths by sex. Rural vital statistical facts presented in the 1936 Report are absent from the Report under review (see this Bulletin 1936 Supp. p. 106*).

Government Officials of British nationality numbered 849 one was invalided, and one died. Other Government Officials included 4,243 *Sudanese* 539 *Egyptians* and 45 *Syrians*. Eleven Sudanese were invalided and 8 died 8 Egyptians were invalided but no invalidings or deaths were recorded amongst Syrian officials.

The average strength of the *Sudan Defence Force* was 4 444. During the course of the year 3,638 N.C.O.s and men were admitted to hospitals cases included 748 for *malaria* 117 for *unspecified fevers* 592 for *venereal diseases* and 822 for *wounds and other injuries*.

Maternity and Child Welfare Work—Ante-natal clinics have been established in most towns in the Northern Sudan to supplement the work already carried out at the local Hospitals. At the Omdurman Clinics 1,592 of the 4,229 attendances recorded were new cases. The returns of the Civil and C.M.S. Hospitals in Omdurman, the Midwifery Training School and the trained midwives show that 1 482 confinements

were dealt with and 15 maternal deaths (during a period of eight months only). It is said that approximately 80 per cent of pregnant women in Omdurman attended the ante-natal clinics during the year under review. In Khartoum and North Khartoum District there are 5 clinics and at these centres 4710 attendances were recorded of which 1341 were new cases. The clinics at the four centres in the Northern Province were well attended in these areas there are 28 trained and 119 licensed midwives. New clinics were opened at Kassala (Kassala Province) and Juba (Equatoria Province) and are functioning successfully.

At the *School of Midwifery, Omdurman* 35 pupil midwives completed the course of training and all passed the qualifying examination two midwives attended a revision course. Trained midwives in rural areas are making satisfactory progress. Arrangements have been made to open a subsidiary school at Juba where midwives will be trained for service in the Northern Sudan.

School Hygiene—The School Medical Service has been extended in most Provinces of the Northern Sudan. During the year 332 schools were visited and 2644 pupils were medically examined. The results of these examinations are classified for Districts and Provinces and the percentage findings noted for disease conditions seen. In the Northern Sudan *trachoma* is responsible for the majority of cases referred for treatment while in the South a high percentage of school children suffer from chronic *malaria* and *ankylostomiasis* (see this *Bulletin* 1938 Supp. pp 110*-116*). About 10 per cent of the children in the Northern Sudan have carious teeth and in Equatoria Province the incidence of skin disease suggests a lack of attention to the cleanliness of bodies and clothes. In some areas slight but definite signs of improvement in physique are noted.

In Khartoum Province 33 schools were inspected and 5601 children were medically examined. Only one Girls' school was visited.

Public Health Sanitation etc—The Report under review contains an admirable *Historical Survey of the Development of the Sudan Medical Service* from the conquest and re-occupation of the country in 1899 to the present day.

Throughout 1937 the public health of the Sudan was satisfactory. Beneficial rains gave the country its sixth successive year of good harvests the population enjoyed a state of reasonable prosperity and there was an absence of any serious epidemic outbreak. Sanitary services have been extended and consolidated in many areas and *latrine* accommodation increased and improved in most Provinces. Improvement in village sanitation recorded. In the Northern Sudan it is said a notable improvement in the cleanliness of towns and villages is observable. This has resulted through the efforts of an increase in supervisory staff and the willing co-operation of the native administration. Local committees for the improvement of health have been established in the principal district headquarters and provincial boards unify sanitary control and expenditure. Preventive medicine continues to develop and an adequate supervisory sanitary staff is being trained as rapidly as possible to meet the needs of the whole country.

Purification plants and piped water supplies are installed at Khartoum Khartoum North Omdurman Atbara Port Sudan

Wad Medani Abu Usher and Juba. The Egyptian Irrigation Colonies at Malakal, Gebel Aulia and Gordon's Tree Dockyard are similarly provided for constructional works in connexion with supplies to Wadi Halfa are in progress, and schemes and plans applicable to Torit and Malakal Town are in course of preparation. Routine examination of established supplies continued to give satisfactory results. A central committee established in Khartoum has studied the problem of native housing with a view to discovering types suited to local needs and which will satisfy public health and economic requirements. Plans of various types have been prepared and circulated for criticism by British and Native Officials. Models are in course of preparation and demonstration houses are to be erected at various centres. A programme of slum clearance designed to spread over three years has been initiated in Halfa. Steady progress in similar areas elsewhere in the Northern Sudan is reported. In Juba a marked fall in the incidence of malaria amongst northern officials is directly attributed to improved housing.

Two additional *Sudanese Sanitary Officers* qualified during the year and were posted to provinces. A sanitary officer is now at work in all provinces where British staff is not available (see this *Bulletin* 1938 Supp. p. 111). *Sanitary Overseers* are junior qualified Sudanese Officials, who in the larger towns work under the supervision of British Sanitary Inspectors or Sudanese Sanitary Officers. Elsewhere they function independently. In 1935 arrangements were made for suitable candidates to undergo a course of instruction in Khartoum and to pass a qualifying examination. It was estimated that 70 appointments would be necessary to meet the immediate public health needs of the country. 51 of these posts have been filled and with few exceptions appointees have proved an unqualified success. To meet the needs of the Southern Sudan it is essential that personnel shall be recruited and trained locally. A training class for this purpose has been organized at Juba. Successful candidates at the end of the course of training will be posted to districts from which they were recruited.

Port Health Work Quarantine etc.—During the year 1,174 ships entered Port Sudan. No ships were quarantined nor was any person isolated from ships. Quarantine measures were enforced against arrivals from Bombay on account of smallpox, and against arrivals from Bangkok on account of cholera. Quarantine work at Port Sudan is dealt with by a Medical Officer working under the supervision of the Senior Medical Inspector while Port Sanitation is in charge of a British Sanitary Inspector holding special qualifications for this branch of work. During the pilgrim season a Medical Inspector and a Medical Officer are posted to Suakin (where also an Assistant Medical Officer is in permanent residence) for all Sudanese and West African pilgrims for the Hedjaz in transit through the Sudan must leave and return via the Suakin Quarantine Station. During the year 1,728 Sudanese and 4,618 West African pilgrims passed through the Station, all were vaccinated and inoculated against cholera. The general health of the 4,929 pilgrims returning from the Hedjaz via Suakin was good. 85 were admitted to hospital and 5 died. At the Wadi Halfa Quarantine Station 1,667 Egyptian labourers were dealt with, one was rejected as unfit and 89 were found to be infected with *shikaris* and received treatment.

The sanitary control of aircraft continued along lines previously described (see this *Bulletin* 1938 Supp p 112*) During the year the 873 insects collected from commercial aircraft arriving included 824 Diptera of which only 7 were mosquitoes

Hospitals Dispensaries etc—Medical work carried out in hospitals and dispensaries continues to increase it is believed that the figures for in and out patient treatments will remain established at about the present record (see below) and it is not intended to increase facilities for treatment in the near future (see this *Bulletin* 1938 Supp p 112*) but extensions have been planned to meet special exigencies It should be added that the great majority of the hospitals in the Sudan now have clinical laboratories staffed by trained Sudanese laboratory assistants

At Omdurman the new Out patient Department for men and an additional wing of 50 beds were opened during the year Additional ward accommodation has also been provided at Port Sudan and a new out patient department and a ward for women were opened at Juba. Overcrowding in the wards at the Malakal Hospital was reported at the beginning of the year and an increase in the volume of work at the Abu Usher Hospital. Two of the Khartoum Hospitals need to be replaced According to the classified returns there are now 38 Hospitals and 346 Dispensaries in various parts of the country with an aggregate accommodation of 5 494 beds.

Of the eight *Medical Mission Institutions* 4 are maintained by the Church Missionary Society 3 by the Sudan United Mission and one by the American Mission.

The volume of work dealt with at all treatment centres reads as follows —

Item	In-patients						Out patient Attendances
	Europeans	Deaths	Non Europeans	Deaths	Total Cases	Total Deaths	
38 Government Hospitals and 346 Dispensaries							
C.M.S. Hospitals	405	7					
Sudan United Mission Hospitals	?	?	100 683	2,167	101 083	2,174	6 675 889
American Mission Hospital	?	?	?	?	2,167	?	196,303
	?	?	?	?	556	?	15 494
					20	?	10 178

Special attention is being paid to the better *training of staff* the training of Assistant Medical Officers Sanitary Overseers Nurses and Midwives and other personnel continued throughout the year During 1937 no new students were admitted to the *Kitchener School of Medicine* where the 18 students under training comprised 16 medical and 2 sanitary students Eight students sat for examination in Public Health and Pathology eight were examined in physiology and two sat for the Diploma examination of the Royal Sanitary Institute with the exception of one candidate in the Public Health and Pathology examination all were successful.

The Sudan with its thousands of miles of land frontier and its constant and varied traffic by many and devious routes which combine to render efficient quarantine control impracticable is specially vulnerable to the introduction of epidemic diseases from neighbouring countries. The year 1926 saw the introduction of *relapsing fever* from the West, and for four years the disease ravaged the population of Darfur between 1928 and 1930 thousands of cases of *smallpox* owed their origin to infection introduced by French immigrants. These two diseases again made their appearance towards the end of 1937 through the agency of infected labourers returning from Eritrea and Abyssinia. Of *smallpox* 425 cases with 57 deaths were reported, 231 of the cases and 41 of the deaths occurring in the Blue Nile Province and 103 cases with 10 deaths in Kordofan Province. West Africans from Abyssinia and Eritrea carried the disease to Kassala Province where 50 cases and 6 deaths were recorded. An extensive vaccination campaign was organized in each of the infected areas. 561 198 vaccinations were performed, 311 881 of these in the Blue Nile Province alone.

In the words of the Report, "West African immigrants with *relapsing fever* provided a constant stream of infection to Kassala and Blue Nile Provinces throughout the year." Altogether 374 cases and 48 deaths were reported of these, 191 cases with 12 deaths occurred in the Blue Nile Province 65 cases and 10 deaths in Kassala Province and 68 cases with 24 deaths in Darfur Province. Delousing stations were established at various centres and 25,381 persons were dealt with during the year.

Cases of *cerebrospinal meningitis* were reported from every Province, though the country was spared the devastating epidemics which ravaged the Western Provinces during the period 1834-1836. With the exception of an isolated outbreak in the Awel District of Equatoria Province the disease remained sporadic and showed no signs of assuming epidemic proportions. Altogether 446 cases and 293 deaths were reported (see this *Bulletin* 1938 Supp. p. 113*).

Plague and *typhus* have not so far been reported in the Sudan and no case of *cholera* has occurred for many years. Strict anti-plague measures are enforced at Port Sudan and elsewhere rat-infestation is kept within reasonable limits.

The incidence of *malaria* which was high in the Northern Sudan at the end of 1936 (see this *Bulletin* 1938 Supp. p. 112*) fell in January 1937 and remained below the average for the remainder of the year. The anti-malarial staff in this area has been considerably strengthened in recent years. In the Gezira and adjacent areas of the Blue Nile Province the investigations of the malarialogist are yielding results of practical application. In every part of the Sudan efforts are being made to popularize the use of a cheap and efficient insecticide and nets among the general population. The classified results of medical examinations of school-children show that the splenic index figures range from 0.4 per cent. to 54.8 per cent.

Hospital Returns show that 144 694 cases of malaria were treated during the year of these 7,883 were in-patients and 39 died. At the Stack Medical Research Laboratories where 1 691 blood films were examined 189 were *subtertian* infections, 58 *benign tertian* and 6 *quartan*. The Government Entomologist, Mr H. W. BENDROD

describes work concerned with the survey of mosquitoes in Khartoum and Urban District and in greater detail the continuance of the mosquito research in the Gezira (see this *Bulletin* 1938 Supp p 118*)

Of *blackwater fever* 20 cases with 5 deaths were notified.

Enteric fever was responsible for 165 cases and 17 deaths two of the cases and two of the deaths occurring amongst Europeans of the total cases recorded 78 were notified in Khartoum Province, 49 in Omdurman alone. At the Stack Research Laboratories where Widal tests were applied to 850 samples of serum, 145 reacted positively with *Bact typhosum* while among 480 blood cultures 72 gave positive findings with *Bact typhosum* infections 5 *Bact paratyphosum A* and 1 *Bact paratyphosum B*

There were 2 642 admissions to Hospitals on account of *dysentery* and of these 2,504 were *amoebic* and 139 *bacillary* infections. Seventeen of the cases occurred among Europeans and all the 53 deaths recorded occurred among non Europeans. Examination of 1,298 faecal specimens at the Stack Laboratories showed the Flexner Y bacillus in 35 cases Shiga's bacillus in 5 that of Schmitz in 3 amoebae in 13 and ova in 57

The incidence of *kala azar* appears to be increasing it is difficult to determine to what extent the increase is due to the development of medical work in areas where special attention has been devoted to the disease in recent years. Altogether 333 cases were reported (all non Europeans) with 57 deaths. In the Blue Nile Province there were 148 cases as compared with 111 in 1936 and in Gedaref (Equatoria Province) 50 cases as against 13 in the preceding year

It is said the incidence of *tuberculosis* shows no increase despite increasing risk of infection from outside the Sudan this is attributed to the general raising of the standard of living which has increased the resistance to the disease of the population as a whole. Altogether 883 cases were admitted to Hospitals and 188 died 488 of the cases and 148 of the deaths were ascribed to the pulmonary form of the disease Two non fatal cases of pulmonary tuberculosis occurred among British patients who are said to have contracted the disease in Egypt

Dr A R McHELVIE the Ophthalmic Surgeon contributes the usual *Ophthalmic Report* in which he sets out in great detail the record of the year's work. At the River Hospital where 88 beds are provided for ophthalmic cases 653 in-patients were treated new cases among out patients numbered 7 640 and 35,938 attendances were recorded at the Omdurman Hospital there were 97 in patients, 3 777 new cases among out patients and 90 180 attendances recorded. Among the 653 in patients at the River Hospital 78 were treated for *trachoma* and among the 7 640 new out patients 2 018 were treated for this condition in all Hospitals in the Sudan no less than 262,574 in-patient and out patient cases of *trachoma* were treated during the year under review

Sleeping sickness remains endemic in the Zande District of Equatoria Province (see this *Bulletin* 1938 Supp p 115*) Of the 89 cases recorded 63 were reported from the Zande District—where for some years the most rigorous and irksome restrictions have been imposed yet re-infections continue from outside the Sudan—and 23 from the Kajo-kaji sub-district. The disturbing increase in incidence in the

latter area (where in 1936 only 8 cases were reported) suggests that the local fly is infected in spite of the Pass System (see this *Bulletin* 1938 Supp., p. 115*) illicit movement still takes place across the border into the heavily infected Aringa area of Uganda. A thorough inspection of the whole district is in progress. It has been decided to relax certain measures which are definitely irksome to the inhabitants and to concentrate on intensifying such precautionary measures as the distribution of population in selected areas, clearing of streams, tsetse fly destruction, etc. To this end an Assistant District Commissioner has been appointed to deal with the administrative work in connexion with sleeping sickness prevention, and the cadre of public health officials has been increased.

Helminthic diseases—Hospital and Dispensary Returns supply the following data relating to patients treated for three specific infections, etc. —

	Schistosomiasis	Amoebiasis	Dracontiasis
In patients only	1,974 (8 deaths)	220 (11 deaths)	731 (1 death)
In-patients and out-patients	11,974	3,041	2,969

Schistosomiasis (*S. haematobium*) is said now to be of little public health importance in the Sudan though it is only by constant efforts in certain areas, notably the Gezira, that incidence is kept at a low level and repeated infections are prevented. Special attention is now being devoted to Wadi Halfa (Northern Province) and the Duedin and Korti districts (White Nile Province) where annual examinations of the people, regular treatment, the re-siting of villages and the provision of clean water supplies and sanitary latrines are among works to be undertaken in an effort to diminish incidence and intensity of the infection. Of the 11,974 cases dealt with during the year it is noted that 3,875 were recorded in the Northern Province, 2,630 in Kordofan Province and 2,360 in the Blue Nile Province. The following additional facts are supplied for specific areas —

	Number examined	Number infected	Percentage
Northern Province			
Dongola and Marowe	45,741	1,133	2.5
Wadi Halfa	18,490	2,002	10.8
Blue Nile Province			
Gezira Adults	30,768	28	0.08
Children	10,039	63	0.62
Total	40,806	86	0.22

It is said that *S. mansoni* infections of a mild and in some cases apparently symptomless type are commonly encountered in the Equatoria Province (Southern Sudan) but that it has been difficult to find any possible snail hosts. An investigation carried out in the Province showed that *Physopsis diuersi* was readily found, often in large numbers and it is believed that this snail must be the chief if

not the only vector of *S. mansonii* infections in the Equatoria Province even though up to date no specimen infected with *S. mansonii* has been found.

Ancylostomiasis is a disease of no public health importance in the Northern Sudan but is a serious problem in the South especially in certain districts in Equatoria Province. Of the 3 044 cases reported during the year 2 277 occurred in the Equatoria Province (see also this *Bulletin* 1938 Supp. p. 116*). The usual measures are being taken to reduce the incidence of the disease. *Dracontiasis* continues to be prevalent in the Southern Sudan and the Nuba Mountains. In Equatoria Province 2 744 cases were treated during the year progress is reported in the construction of wells in the Juba and Yei Districts of this Province (see this *Bulletin* 1938 Supp. p. 116*).

Of *leprosy* the Report observes. There is no evidence of any increase in the incidence. During the year seven new leper settlements were opened in the Nuba Mountains where the incidence of the disease has always been high. The whole of this area is now covered and it only remains for sufferers to take advantage of available facilities. All the leper settlements are run on an entirely voluntary basis by making them attractive it is hoped that patients will voluntarily seek treatment and perhaps remain in the settlements so that gradually a large percentage of infectious lepers will in course of time be isolated. The system of home isolation continues to function satisfactorily in the Northern Sudan and in the words of the Report with all its defects is more satisfactory and humane than any system of compulsory or voluntary segregation.

According to published data at the end of the year there were 2,244 lepers in camps or settlements, 128 under observation or treatment and an estimated total of 8 722 cases in the whole of the Sudan. Of the total cases 5 793 are assigned to the Equatoria Province where are established the large settlements of Li Rangu and Source Yubo (see this *Bulletin* 1938 Supp. p. 116*).

11 deaths were ascribed to the disease. Of 383 persons actually bitten two were bitten by a rabid man 351 by dogs, 15 by cats, 10 by donkeys, and 2 by camels among the 11 fatal cases 9 had been bitten by dogs, one by a wild cat and one by a camel. A case of canine rabies was confirmed for the first time from the Zande District, where it is believed the disease has been prevalent among the dogs there for some time. At the Laboratory where 140 brains were received and examined, 48 were positive for Negri bodies the distribution being 29 dogs 10 donkeys, 4 oxen, and one each for sheep camel mule horse and human. The steps taken to eliminate the vector of *yellow fever* continue the *Aedes aegypti* survey has been extended to all parts of the Sudan and frequent inspections of likely breeding places carried out these inspections totalled over 4 millions during 1937. At the Laboratory work was continued along the lines previously described (see this *Bulletin* 1938, Supp. p. 117* and below under *Scientific*). Outbreaks of *influenza* of a virulent type occurred in all districts of Equatoria Province and the Nuba Mountains with high mortality while minor outbreaks of a mild type occurred in the Northern Sudan. The only available facts relate to in-patient cases these comprise 23 non-fatal European cases and 1 367 non-European cases with 18 deaths. Of *diphtheria* 36 cases were reported the disease was reported for the first time in the Equatoria Province. *Undulant fever* was responsible for 33 cases and one death 13 of the cases occurred in Kassala Province and 10 in Blue Nile Province. Nineteen cases of *scarv* 21 of *pellagra* and 274 of *acute rheumatism* were recorded. Tumours accounted for 748 cases of which 177 were defined as malignant and 571 as benign. In-patient cases of *pneumonia* numbered 2,472 and hospital deaths due to this cause 283 one non-fatal European case is mentioned.

Scientific—The Report of the *Stack Medical Research Laboratories* contributed by Dr E. S. HORGAN records that 20 541 specimens were received examined and reported upon during 1937. The results of some of these examinations have been the subject of mention in the preceding notes under such headings as *malaria enteric fever dysentery helminths venereal diseases* and *rabies*. It is necessary to refer to some of the important research activities of the Laboratories these are described in great detail in the Report under review though references for present purposes must necessarily be brief.

Although from time to time cases of *anaplasma fever* have been reported, no real clinical evidence indicated that such were Rickettsial infections. With a view to determining whether the absence of clinical typhus in the Sudan is apparent or real, during 1937 human sera were obtained from all parts of the country and rat sera from the larger centres of population in the Northern Sudan and the Weil-Felix reaction applied to 1,000 specimens of the former and 240 of the latter. The serological results appear to confirm the clinical findings that fevers of unknown origin in the Sudan are most unlikely to be due to Rickettsial infections.

Jawadzia is a clinical condition frequently met with in the Sudan but Weil's disease has not been found in any instance. During 1937 a survey among the rats in the Northern Provinces was undertaken and 200 rats were examined results failed to show any evidence of leptospiral infection among them.

The prevalence of *relapsing fever* among returning labourers frombyssinia and Eritrea provided opportunities for carrying out studies of the infecting strains. *Yellow fever* investigations continue.

G M FINDLAY of the Wellcome Bureau of Scientific Research visited the Sudan in the early months of the year and collected further series of human and animal sera from the Nuba Mountains and Sennar districts. A million doses of *vaccine lymph* were manufactured during the year. Research work included the investigation of the treatment of lymph by chloroform as a bactericidal agent and the effect of high air temperature on potency. During the year a certain amount of work on the *preservation of cultures* frozen and dried in vacuo was carried out.

Mr H. W. BEDFORD, Government Entomologist, supplies a detailed account of the year's work of the Section of Medical Entomology. In his survey of insects of medical importance he records a large increase in the numbers of mosquitoes sent in for determination. Among 3,392 specimens identified 218 were Anophelines and 3,174 Culicines of the latter 346 were *Aedes aegypti* while a species new to science *Anopheles (Myzomyia) ripiculus* was collected and described by Mr D J LEWIS and specimens new to the Sudan were also collected. Apart from insects collected from aircraft (see above *Port Health etc*) the more than 500 specimens determined included 400 tsetse flies (*G. palpalis* and *G. morsitans*) numerous fleas Tabanidae Chironomids and other biting flies. The finding of large numbers of the tick *O. savignyi* at Shambat is worthy of note. Mr D J Lewis continued his mosquito survey in the Gezira with a view to determining whether a further knowledge of the bionomics of *A. gambiae* and *A. pharoensis* under the unique Gezira conditions could add to the efficiency or reduce the cost of present control measures.

Financial—No details supplied.

MEDITERRANEAN

PALESTINE (1937)

Palestine, on the western edge of the continent of Asia at the eastern extremity of the Mediterranean Sea, is bounded by the Mediterranean on the west, Syria on the north, Trans-Jordan on the east and the Egyptian Frontier District of Sinaï on the south. It has a total area of about 10 100 sq miles (somewhat larger than that of Wales). The chief town and seat of government is Jerusalem. Other important towns are Gaza, Tel-Aviv, Acre, Jaffa and Haifa, the last two being also the chief ports. Palestine is administered under a Mandate from the League of Nations.

Total Statistics.—Including the Bedu tribes, the mid-year populations in 1937 were estimated to be Moslems 875,947 Jews 388 084 Christians 109 789 Others 11,520 making a total of 1,385,320. The tabulated facts published in great detail in the Report under review deal with the settled population only (i.e. excluding the Bedu tribes enumerated in 1931) and are as follows —

Community	Mid-year Population	Births	Birth Rate	Deaths	Death Rate	Infant Deaths	I M R.
Moslems	808 394	40,261	49.7	20,091	24.8	7,219	179.3
Jews	388 084	10,297	26.7	3,003	7.8	586	57.2
Christians	109 789	3 663	33.5	1 537	13.9	469	126.3
Others	11,520	508	44.1	263	22.8	61	179.1
Totals	1,316,797	54 749	41.6	*4 864	18.9	8,305	152.8

The general death rate and the infant mortality rate both show increases over the corresponding rates for 1936. It is pointed out that there is much poverty among the Arabs both in towns and villages, and that the low state of nourishment amongst Arab women is a direct cause of the increased infant mortality. Jewish death and infant mortality rates show improvement.

Of the total deaths registered 8,854 were certified as to cause by medical practitioners and of these 25 per cent were due to *respiratory affections*, 21 per cent to *diarrhoea and enteritis* and 9 per cent. to *infectious and parasitic diseases*.

Maternity and Child Welfare Work.—To the Princess Mary Maternity Wards of the Government Hospital Jerusalem 593 cases were admitted, and 542 live births, 22 stillbirths, and 4 maternal deaths recorded. In the British Section of the same Hospital there were 23 deliveries. At the Haifa Hospital 203 maternity cases were dealt with, while at the Jaffa, Nablus and Gaza Hospitals, where accommodation for maternity cases is very limited, there were 91 admissions for delivery. The District Maternity Service in the Old City Jerusalem, also dealt with 132 deliveries of women in their homes. The *Women's Clinics* at Jerusalem, Jaffa, Haifa and Nablus continued to be very popular and large numbers attended but the weekly journeys of the Lady Doctors by road to Jaffa and Nablus were not unattended with risk owing to the disturbed state of the country (see also this *Bulletin* 1938 Supp. p. 119*).

The Medical Department maintains 28 *Infant Welfare Centres* in towns and villages, participates in the administration and operation of four which are supported in part from voluntary sources maintains or controls centres under the Superintendents of Midwifery in six towns and makes an annual subvention towards the maintenance of Jewish Welfare Services. New village clinics were opened at four centres. The volume of work dealt with at different centres may be summarized as follows —

Supporting Organization	No of Centres	Children on Registers	Attendances Recorded	Home Visits by Nurses
Government and Municipal	34	9 838	298 761	95,857
Hadassah Medical Organization	15	2 492	58,911	17,697
Jewish Federation of Labour	18	2,466	38 127	3,525
Women's International				
Zionist	5	691	13 193	1,315
Local Committees	6	1 323	32,362	12 802

At the *Midwives Training School* Jerusalem Government Hospital 9 graduate nurses and 7 pupil midwives completed the course of training and 8 nurses completed the prescribed course in midwifery at the training school of the Hadassah Medical Organization. The supervision of licensed midwives and *dayas* (unqualified midwives) continued as previously described (see this *Bulletin* 1938 Supp. p. 120*). It is said that licensed midwives are finding it increasingly difficult to earn a livelihood from practice owing to the competition from hospitals, etc.

School Hygiene.—The provision for Government school medical inspections remains inadequate (see this *Bulletin* 1939 Supp. p. 120*) but within the limits of available service valuable work was done. During the year 29,989 children (out of 53 376 on the registers of 442 schools) were medically examined in town and village schools. *Trachoma* remains the most common disability met with 59 per cent of the children examined in town schools and 73 per cent in village schools suffered from this condition while 10 per cent of the children in town schools and 3 per cent in village schools suffered from other eye diseases. Three additional school nurses have been appointed and are undergoing a special course of training in ophthalmic nursing attendances of children for ophthalmic treatment during 1937 totalled 2,906,852. On account of the high prevalence of typhoid in Jerusalem about 50 per cent. of the school-children were given T.A.B. inoculation.

The usual examination of school-children for splenic enlargement was carried out among 38 792 children attending town schools the spleen rate was 1.5 per cent. and among 43,883 children in village schools 4.7 per cent.

The premises of all registered schools are inspected annually and reports made on defects affecting sanitation and hygiene overcrowding is said to be a common feature.

Lectures on hygiene were given by Medical Officers to teachers and lectures on mothercraft and hygiene given to the students at the Women's Training College and to pupils of senior classes.

Public Health Sanitation etc—Owing to financial stringency there was no material development in the services of the Department except in services for which the Government was already committed. The state of the health of both the Arab and Jewish communities was fairly satisfactory in spite of the privation experienced by the poor of both sections of the population (see *1934 Statistics* above). In spite of disturbances throughout the country *anti-malarial work* was carried out as usual. Anti-malarial drainage schemes were limited to completion of a section of the Birket Ramadan scheme draining of Birket Hanoun and filling of low land on Lake Tiberius. Local authorities carried out several works of drainage under supervision of the Department. The increased strength of the military forces and their disposition in various parts of the country necessitated control work in areas hitherto not considered essential.

The *sanitary services of the principal towns* are said to have functioned satisfactorily though it is pointed out that with the single exception of Jerusalem, main drainage does not exist. In Jerusalem lack of capital has greatly hampered the laying of lateral extensions but a number of connexions to the main sewer were effected by property owners and work on the Bethlehem road sewer was commenced. Main drainage schemes have been planned by the Consulting Engineers for a number of towns and improvements effected in some local areas. Financial provision for *village sanitation* was considerably reduced but with available funds 1,965 bore-hole and 1 149 tar barrel latrines were installed.

The *water supply of Jerusalem* functioned satisfactorily and was maintained uniformly pure by means of the softening and filtration plant which was completed (see this *Bulletin* 1938 Supp. p 121*). The reports of the Consulting Engineers upon the Tel-Aviv and Jaffa main supply schemes are being considered by Government. Experimental borings have been successful in discovering adequate and satisfactory sources of supply for Haifa. With the limited credits available for the improvement of *village water supplies* 13 approved schemes were completed.

The scheme for the *housing of labourers* in Haifa (see this *Bulletin*, 1938, Supp. p 121) was brought into effect with very satisfactory results. It is hoped that the procedure adopted in Haifa will be carried out also in Jaffa. With the passage of the Public Health (*Rules as to Food*) Ordinance the Department was enabled to exercise a much stricter control of food products of all descriptions than formerly. The *Milk Trade* shows distinct signs of improvement, but progress is hampered by the difficulty of controlling supplies of the small producer and by the lack of public demand for better milk. Large quantities of good quality butter are imported, but in some cases it is adulterated before sale to the public. Particular attention is devoted to standard requirements in respect to this and other foods. The inspection and licensing of premises, and the analyses of samples of foodstuffs were continued. Details of this work are set out in a series of tabulated statements.

The staff of the *Railway Medical Service* remained unchanged. Routine work was carried out along lines previously described. Attendances of railway personnel at clinics of Medical Officers totalled 15 463 and of these 10,572 related to new cases.

Port Health Work—A new feature relates to the development of the Tel-Aviv jetty and lighter harbour section of Jaffa Port and the organization of quarantine establishments and staff permitting the operation of services as a separate entity from those at Jaffa. Quarantine restrictions were imposed against arrivals from ports in India, Malta and Siam on account of cholera plague and smallpox in those places. An increase of shipping traffic was reported at Jaffa and Tel Aviv 1,589 vessels and 2,573 passengers were dealt with at Haifa 2,436 vessels and 35,112 passengers while 378 vessels were examined in the Acre and Gaza roadsteads.

Air traffic continues to increase and during the year 1,735 aircraft were dealt with. Supervision is carried out at Gaza, Lydda and Haifa airports towards the end of the year Tiberias on the Sea of Galilee was brought into use as a landing place for the Eastern Flying Boat Service.

The medical surveillance of travellers and immigrants entering the country was continued. 48,502 persons were dealt with and 94 per cent traced to their destinations. The Moslem pilgrimage to Mecca proceeded as usual under arrangements which have been described in previous Reports. 424 Palestinians and 24 Trans-Jordanians made the pilgrimage.

Hospitals, Dispensaries, etc.—With the exception of work upon the new Haifa General Hospital and minor alterations to existing buildings in other places, new constructions previously approved were again deferred with the result that in the absence of material increase in accommodation, gross overcrowding occurred in many Government Hospitals (see this *Bulletin* 1938 Supp. p. 122*). To provide for the needs of the increasing population in Palestine more accommodation is urgently required in a number of hospitals. The Gaza Municipal Hospital was taken over completely by the Department in lieu of the former and unsatisfactory dual control of Department and Municipality. The construction of the Knapat Cholim Hospital (Jewish) of 64 beds was completed during the year. Although all medical and health services are equally at the disposal of all sections of the community, there has been an increasing tendency during the past 8 or 9 years for Jews to seek admission to Jewish Hospitals. All infectious cases are however provided with accommodation by Government, though a limited number of cases of enteric are permitted in the Tel-Aviv Municipal Hospital.

The volume of work dealt with at various Hospitals during the year under review may be summarized as follows—

Description	Beds	Admissions				Deaths
		Moslems	Jews	Christians	Others	
8 Government Hospitals	622	9,223	1,442	2,502	—	780
Tel Aviv Municipal Hospital	234	3	6,947	4	70	453
4 Prison Sick Wards	72	831	99	54	19	4
29 Voluntary Hospitals	1,912	9,820	18,783	5,189	2,092	1,291
2 Government Mental Hospitals	157	—	4	7	—	5

Exclusive of ophthalmic and other special clinics there are 20 Government and Municipal *dispensaries and out-patient clinics* at these centres 181 487 new cases were treated, these included 9 724 cases of *eye diseases* and 1 912 cases of *malaria*. Moslems accounted for approximately 74 per cent. of the total new cases.

At the 40 *voluntary dispensaries and clinics* established in 11 towns 698 654 new cases were dealt with and these included 118 365 cases of *eye diseases* and 2 893 cases of *malaria*. At these centres Moslems were responsible for only 15 per cent. of the total new cases.

During the year 23 876 *voluntary village clinics* were held and 277 178 new cases were treated among them were 12 330 cases of *eye diseases* and 2 160 cases of *malaria*. At these centres Jewish patients were in the great majority and responsible for 95 per cent. of the total cases.

Ophthalmic clinics operated in 10 principal towns and first-aid ophthalmic clinics functioned in 21 villages with emergency clinics in 3 additional villages the mobile ophthalmic unit operated in 13 villages not served by permanent clinics. During the year 72 673 new cases were treated, *trachoma* accounting for 74 per cent. and *epidemic acute conjunctivitis* accounting for 48 per cent. of the total cases recorded. In addition the ophthalmic sections of general clinics elsewhere in the country dealt with 13 760 and the school medical service with 5 414 new cases of ophthalmic disease.

The number of *nurses in training* at hospitals recognized as training schools steadily increases during the year under review these numbered 281 of whom 128 were in the first year 91 in the second, and 62 in the third year of the prescribed course. Examinations are held twice a year 77 were successful at the first year 36 at the second year and 39 at the third year examinations in 1937.

Of *notifiable diseases* 14 531 cases with 1 634 deaths were reported the incidence of *measles externa* and *whooping cough* was approximately doubled by comparison with 1936 experience. The notes which follow briefly summarize the principal items of morbidity experience commented upon in the Report under review.

The incidence of *malaria* was not unduly high minor epidemics were reported from the vicinity of undrained marshes in a sub-district of Beersheba where 484 cases among Bedouins encamped in that area were recorded. The numbers of hospital in-patients treated for the disease are not stated but there were 4 805 cases of *malaria* treated in public dispensaries among a total of 880 141 dispensary patients treated for all causes of sickness. [In another section of the Report statements of *malaria cases treated read as follows* at Government and Municipal Dispensaries 1 912, at Voluntary Dispensaries 2 893 and at Village Clinics 2 160 making a total of 6 965 cases.] Of *black water fever* two cases and one death were recorded. Brief reference has been made to the routine anti-malarial measures and drainage work carried out (see *Public Health* above) and to the spleen surveys among school-children (*School Hygiene* above). It remains to add that among 10 883 blood films examined at the Laboratory for the presence of *malaria parasites* 693 were *P. vivax* infections 7 *P. malariae* 542 *P. falciparum* and 8 were mixed infections.

No case of *smallpox* was recorded. Protective vaccination against the disease was continued steadily throughout the year and a total of 68 381 vaccinations performed. *Cerebrospinal meningitis* was

responsible for 44 cases and 26 deaths and *acute poliomyelitis* for 18 cases with 4 deaths. *Relapsing fever* gave rise to 40 non fatal cases. Research work at the Laboratory was successful in recovering the spirochaetes of relapsing fever from ticks and subsequently effecting their passage through laboratory animals the transmission of *S. recurrentis* by *O. tholozani* to man was definitely established.

Of *typhus fever* 262 cases and 3 deaths occurred. Among 30,351 samples of serum examined at the Laboratory 404 agglutinated positively with *Proteus* X 19. There was a slight increase in the numbers of cases of *dysentery* 373 cases and 32 deaths were recorded. Among 10 193 pharyngeal swabs examined, *C. dysenteriae* was isolated 1,532 times. There was a large increase in the incidence of *measles* 7 594 cases with 669 deaths being reported but only 116 (non fatal) cases of *scarlet fever* were notified.

Five fatal cases of *rabies* occurred during the year. Anti-rabies vaccine was issued to 40 different provincial treatment centres where 2,592 persons applied for advice and 2 399 received specific treatment. Two of the treated persons died 15 days after completion of the prescribed course. The Laboratory Report contains a detailed account of the activities of the Department's anti-rabies service. For present purposes it must suffice to say that 165 cases of *rabies* among animals were reported and that 18 sub-districts and 145 localities were affected.

There was a considerable increase in the incidence of *enteric fever* 2,250 cases with 201 deaths were reported. 201 of the cases and 7 of the deaths being due to *paratyphoid*. The disease was most prevalent amongst the Arabs in the rural districts of Nablus Tulkarem and Jenin while there was no corresponding increase among the Jewish population, the incidence in Jerusalem as a whole was double that of 1936 (see also *School Hygiene* above). Incidence showed a steady monthly rise until the peak was reached about the end of August. Preventive measures were particularly handicapped in the Samaria district (where incidence still remained high in December) by delayed notifications due to the disturbed conditions. At the Laboratory where estimations of the agglutinin content of 30,531 samples of serum were made 1,344 reacted positively with *Bact. typhosum*, 156 *Bact. paratyphosum* A 165 *Bact. paratyphosum* B and 19 *Bact. paratyphosum* C. It may be noted that *paratyphoid* infections with A and B organisms are practically equal for in addition to the infections diagnosed serologically the A organism was cultivated 44 times from patient's blood, and the B organism 40 times. Research into the efficacy of anti-enteric vaccines prepared in the Central Laboratories continues (see this *Bulletin* 1938 Supp. p. 124*).

Though 373 cases and 27 deaths were reported as due to *dysentery* it is observed that notifications of the disease cannot be relied upon. Among 19 705 faecal specimens examined at the Laboratory positive findings included *E. histolytica* (free) 222 times and *E. histolytica* (cysts) 191 times. The results of cultural examination of 9,359 specimens showed *Bact. dysenteriae* Shiga present on 77 occasions, *Bact. dysenteriae* Flexner Y 438 times Strong 65 times Schmitz 51 times and Sonne 24 times.

New cases notified of *tuberculosis* are said to have numbered 547 and 237 deaths were ascribed to this cause. In another section of

The Report a classification of tuberculous cases in 1937 shows 587 cases in the towns with 172 deaths and 442 cases in villages with 9 deaths, giving grand totals of 1,029 cases and 231 deaths. In yet another place it is stated that the new cases recorded at the principal clinics numbered 331 and of these 238 were due to the *pulmonary* type of the disease the figures are said to represent the Arab community Jewish cases being dealt with by the Jewish Tuberculosis League.

The scheme for a Tuberculosis Service submitted as a result of the survey in 1935 was again postponed and it is regretted that though valuable work is being done in the out-patient departments of Hospitals there is little to report on the prevention and control of what is undoubtedly one of the most important diseases in Palestine. Among 110 specimens of sputum examined at the Laboratory 514 were positive with *Mycobacterium tuberculosis*. Notification of *phthisis* is still incomplete during the year 512 cases and 360 deaths were reported.

Ankylostomiasis shows high prevalence in many Arab villages in the orange growing areas of Jaffa and in the coastal belt. After mass treatment of the villagers re-infection occurs in the orange groves where promiscuous defaecation is common. A scheme for the sanitation of the groves was to be inaugurated in 1938. The campaign for the investigation and treatment of hookworm was continued. 1,963 persons were examined, results showing an average incidence of 48 per cent.

The investigation into the incidence and distribution of *schistosomiasis* was continued (see this *Bulletin* 1938 Supp. p. 125*). During the year 3,442 individuals were examined and of these 303 were found to be infested with *S. haematobium* and only 9 with *S. mansoni*. The Ruben River and the lower reaches of the Anja River both in the Southern District, are the principal foci of the disease. The annual Moslem festival which is held in the Ruben River area attracts many thousands of people from all districts. Treatment of infested waters and propaganda against bathing in such waters were instituted in this and other potentially dangerous areas. The following records of examinations and findings appear in the Laboratory Report—

Among 19,705 faecal specimens 1111 contained *Ascaris*, 1,816 *Trichuris*, 264 *Taenia*, 134 *Ancylostoma* and 36 *S. mansoni*; while among 41,658 specimens of urine microscopically examined only 390 contained *S. haematobium* ova.

Ten cases of *leprosy* were reported—some of these may have included recrudescences of the disease. Among 10,183 naso-pharyngeal smears examined 39 were positive with *Mycobacterium leprae*.

Veneral diseases.—The Venereal Clinics at Jerusalem, Jaffa, Haifa, and Nabulus functioned with increasing popularity. 1,696 cases of *syphilis*, 78 of *soft chancres* and 385 of *gonorrhoea* were treated during the year and 37,020 attendances for treatment were recorded. The two British Women Medical Officers have made considerable progress in extending treatment for venereal diseases amongst women though the facilities for the treatment of female patients are still inadequate. The campaign against endemic *syphilis* in the Hebron sub-district proceeded satisfactorily (see this *Bulletin* 1938 Supp. p. 126*). The appointment of a Palestinian Woman Medical Officer for work amongst women in the area is reported to have proved a signal success.

The results of the work carried out at various centres are tabulated in detail. With regard to the serological diagnosis of syphilis 1,279 out of 11,308 specimens of blood serum examined by the M.R.C. No. 1 method reacted positively. In doubtful cases Kahn tests were also applied, positive results being obtained in 196 out of 833 specimens of serum examined. Among 2,252 urethral and vaginal smears examined microscopically, 373 were found to contain *N. gonorrhoeae*.

Scientific—The Central Laboratories of the Department of Health continued to function along lines previously described (see this *Bulletin* 1938 Supp. p. 126*) but it is observed that in view of the rapid development in all branches of the Bacteriological Division extension of present accommodation will soon be imperative while a modern animal house should replace present makeshift buildings to accommodate the large numbers of experimental animals in routine use.

The Bacteriological Division reports a record year's work with 268,537 specimens submitted for routine diagnosis. The principal of these have already been referred to in the preceding notes under such headings as *malaria relapsing fever typhus helminths venereal diseases* etc. In addition the Division prepared, standardized and issued the large supplies of prophylactic vaccines etc. required in the country.

In the Entomological Division where the work is necessarily of a routine character the identification and classification of insects of medical importance was undertaken. This included the examination of mosquitos and sandflies and of fleas parasitic on rats trapped at the ports of Haifa and Jaffa. Among a total of 4,028 fleas examined 3,320 were *X. cheopis*.

The Chemical Division dealt with 12,300 samples and these included upwards of 4,000 samples of milk examined at 12 principal centres equipped for the purpose. Other work was concerned with a large number of biochemical specimens, commercial products, agricultural samples etc. submitted from a variety of sources. Findings are classified in a series of Tables.

References have already been made to the research work concerned with the efficacy of anti-enterica vaccines and the recovery of the spirochaetes of relapsing fever from ticks, etc. (see *enteric fever* and *relapsing fever* above). It remains to say that special investigations undertaken by the Chemical Division included the relation of exchangeable cations to active aluminum in the soil, and further work on the influence of neutral salts on the pH of soils.

The following scientific papers were published during the year —

- BAKER (G. W.) & PUFFLES (M.). Analytical data on Palestinian olives and olive oil — *Analyst* 1937 Vol. 62, p. 604.
 PUFFLES (M.). Some data on Mediterranean red soils — *Soil Science* 1937 No. 2, p. 44.
 — The influence of a neutral salt on the pH of soils. — *Hadar* 1937 No. 11, p. 10.

Financial—The estimated expenditure of the Department of Health for the financial year (April 1st 1937—March 31st 1938) is given as £P.215,223 a sum which represents 4.2 per cent. of the total estimated expenditure of the Government over the same period.

EMIRATE OF TRANS-JORDAN (1937)

Trans-Jordan, which is administered under the same Mandate as Palestine is a strip of country bounded on the west by Palestine, on the north by Syria, on the east by Iraq and on the south by Saudi Arabia, with access to the Red Sea at Akaba. Its area is unknown as the boundaries are not definitely determined. Amman, the capital, is on the Hedjaz railway.

Vital Statistics—No census of the population has yet been taken including the nomadic and semi-nomadic tribes the population is roughly estimated to number 300 000. During the year 11 496 *births* and 6,342 *deaths* were notified to the Department of Health, the resulting crude birth and death rates being 38.3 and 21.1 per 1,000 respectively. The *infant mortality rate* was 203 per 1 000 live births (for towns the rate was 178 and for villages 210 per 1 000 live births). The Report provides classified birth, death, and infant mortality returns for towns and villages in the various Districts: deaths are classified in eight age-groups.

Maternity and Child Welfare Work—The Government has appointed *qualified midwives* one for each of five municipalities: the towns of Amman and Es-Salt also employ one midwife each.

There are two *Infant Welfare Centres*: one at Amman, the other at Zerka. At the Amman centre 129 new cases were registered during the year: 8 767 attendances recorded and 2,465 visits paid to the homes of children. The Zerka centre is entirely administered by the Trans-Jordan Field Force: the Senior M.O. of the Force is in charge, assisted by a qualified nurse and midwife. The work is not confined to the families of the Force but extends to include civilians from neighbouring villages and Beduin tribes: over 3 000 civilians were treated during 1937.

School Hygiene—Medical Officers of Health examined 7 005 school-children and found 1,994 to be suffering from *trachoma* and 243 with enlarged spleens. Attendances at the School Ophthalmic Clinics totalled 353 460. In another section of the Report it is stated that 9,881 children were examined in 166 towns and villages and showed spleen rates ranging from 0.27.2 (the latter in Jerash District) with an average spleen rate of 10.4 per cent.

Public Health Sanitation etc—The establishment of the Department of Health was increased by the addition of one Medical Officer, three Anti Malaria Sanitary Sub-Inspectors, one Hospital Medical Attendant, one Beduin Sanitary Sub-Inspector and an Ambulance Driver for the Desert Mobile Medical Unit. Routine *anti-malarial measures* were continued throughout the country: details of the work are presented in a series of tabular statements.

The *Municipal Sanitary Services* continued to be administered by District Medical Officers and in spite of limited funds were satisfactorily maintained. In regard to *water supplies* (see also this *Bulletin* 1937 Supp. p. 119*) the following developments are noted. The installation of additional pumping machinery for the Kerak supply: the supply scheme for Ein El-Souk (Jerash town) was completed: arrangements made for a water supply scheme for the Municipality of Es-Salt: a small supply scheme completed for Ajloun Municipality: a small reservoir built in Ajloun District. Public Works Department are preparing a supply scheme for Mahas village (Es-Salt District).

Premises engaged in the manufacture and sale of *foods and drinks* are regularly inspected details of visits made are set out in a series of classified statements.

Officers of the Department of Health were responsible for the medical services of the Trans-Jordan section of the *Hedja Railway* and continued to have charge of all medical and public health services pertaining to the *Arab Legion* and *Desert Patrol Force*. The general health of the Forces was good admissions to Government Hospitals were 166 with one death and to Voluntary Hospitals 55 with one death. The *Prison Medical Service* is also a responsibility of the Health Department the health of the prisoners was reported to have been good there were 104 admissions to hospitals with two deaths.

Quarantine Services—The quarantine station at Ma'an was opened during the pilgrimage season 190 pilgrims proceeded to and 418 returned from the Hedjaz by land routes. All pilgrims before departure to the Hedjaz are vaccinated against smallpox and cholera.

Hospitals Dispensaries etc—The volume of work dealt with during the year at various treatment centres may be summarized as follows—

Item	Beds	Admissions	Deaths	Out patients (New Cases)
8 Government Hospitals	74	933	51	20 039 (Two Hospitals)
8 Government Dispensaries	—	—	—	24 218
Desert Mobile Medical Unit	—	—	—	6 491
4 Voluntary Hospitals	117	1 823	81	16 383
Electric Co. Clinic	—	—	—	1 013

The *epidemic posts* established at six centres and the *mobile epidemic unit* also dealt with a number of cases (see this *Bulletin* 1935 Supp p 107* 1936 Supp p 111*).

An excellent account is provided of the origin organization and work of the *Desert Mobile Medical Unit* which under the charge of a Medical Officer treats the Beduin sick. Out patients only are treated by the Medical Officer and his four trained Medical Orderlies. Tent Clinics are established during the year at different centres near the largest group of Beduin tents (these encampments range from 50–100 tents). The dispensary car covered over 7 000 miles during the eight and a half months of its service, and during the year upwards of 6 000 new cases were dealt with. *Eye diseases* are common and *trachoma* frequently met with *malaria* was found more particularly among those who had visited the Jordan Valley *sypkulis* occurred mainly in certain families and much of it was congenital *bilharzia* was found occasionally in the south and in all cases the disease had been contracted outside Trans-Jordan. *Anaemia* was almost universal and signs of Vitamin C deficiency were very common. *Tuberculosis* is said to be widely spread among the tribes. This is the first time work of this description has been attempted and though much of it had to be experimental, the venture seems to have been conspicuously successful.

Cases of *infectious and communicable diseases* reported to the Department of Health during the year totalled 6 508 no serious epidemic outbreak was recorded. Cases and deaths due to notifiable diseases are tabulated for each District.

New cases of *malaria* reported during the year numbered 2,791 and 4 deaths were ascribed to this cause (There were 2,791 cases with 17 deaths in the preceding year) It is stated that repetition of recorded cases occurs amongst patients seeking treatment at more than one centre At Government Clinics 1,547 cases and at Voluntary Dispensaries 1,244 cases were treated At these centres diagnosis rests chiefly on clinical symptoms and may include cases of unspecified fevers under the title of malaria. Anti-malarial measures and spleen rates etc have been subjects of brief reference in preceding sections of the present summary.

At the Government Laboratory 1,445 blood films were examined for the presence of malaria parasites 494 were *benign tertian* 203 *subtertian* 3 were *quartan* and 11 were mixed infections.

Cerebrospinal meningitis gave rise to 12 cases with 8 deaths. The special fresh serum was used in every case. There were 14 cases of *typhus fever* with one death. All cases were treated in Government Hospitals and all necessary sanitary measures taken. Of *measles* there were 538 cases and 70 deaths a large number of mild cases escape notification There were 648 cases of *influenza* with 20 deaths, 350 cases of *whooping cough* with 6 deaths and 9 non-fatal cases of *relapsing fever*.

Fevers of the *enterica* group were responsible for 208 cases and 13 deaths 185 cases and 11 deaths were due to *typhoid* and 43 cases and 2 deaths to *paratyphoid*. An outbreak occurred in two villages in the Irbid district and 59 cases were recorded in Amman there were 61 cases *Ea-Salt* 22 cases and Ma'an District 43 cases In all areas 10,250 persons were given T A B inoculations and other necessary health measures were taken At the Government Laboratory 595 specimens of blood serum were examined for the serological diagnosis of *typhoid* and *paratyphoid*. Of these 155 agglutinated *Bact typhosum* 16 *Bact paratyphosum A* 22 *Bact paratyphosum B* and 7 *Bact paratyphosum C*.

Of *dysentery* 219 non-fatal cases were notified. At the Laboratory 67 faecal specimens were cultured *Shiga's bacillus* was isolated in 6 and Flexner's in 2 cases Among 305 stools microscopically examined 5 were positive with *E histolytica* and 6 with *Endolimax Nana*.

Notified cases of *tuberculosis* (all forms) numbered 624 with 33 deaths 363 of the cases and 28 of the deaths were due to the *pulmonary* form of the disease An anti-tuberculosis campaign amongst the Beduin tribes was started after the organization of the Desert Mobile Medical Unit in April 1937 Among 85 specimens of sputum examined at the Laboratory 21 were found to contain *Mycobacterium tuberculosis*. *Pneumonia* was the cause of 156 cases and 30 deaths.

The 600 cases of *venereal diseases* reported comprised 548 cases of *siphilis* and 52 of *gonorrhoea*.

Other diseases mentioned in the Report include the following Three persons in Irbid District bitten by a rabid hyaena developed *hydrophobia* all died. Twenty three persons bitten by animals suspected of rabies received anti rabic treatment. No case of *smallpox* was reported 22,350 vaccinations were performed during the year There were 16 cases of *diphtheria* with 3 deaths at the Laboratory where 89 pharyngeal swabs were examined 3 were positive with

C. diphtheriae Twenty nine non fatal cases of *erysipelas* 130 of *mumps* and 70 of *chickenpox* were notified. The *Ophthalmic Clinic Service* (exclusive of school clinics) treated 12,913 new cases of *eye disease* and the *Voluntary Clinics* dealt with 2,379 new cases.

Scientific—At the Government Laboratory 5,281 specimens of various kinds were examined during the year. The principal specimens and findings recorded have already been mentioned in the preceding notes.

Financial—Expenditure on Department of Health Services for the year 1936-1937 was estimated at £P 15 478 or 3.3 per cent. of the total Government expenditure over the same period.

CYPRUS (1937)

Cyprus, an island in the eastern Mediterranean, lies some 40 miles south of Asia Minor 60 miles west of Syria and 240 miles north of Egypt. Its area is 3,584 sq miles (about that of Norfolk and Suffolk combined). Nicosia its capital lies near the centre of the island.

Vital Statistics—The following facts are supplied —

Area	Estimated Population	Birth Rate	Death Rate	Infant Mortality Rate
(a) <i>The Colony</i>	370 933	29.5	17.0	159.3
(b) <i>Districts</i> —				
Nicosia	120 031	28.2	16.6	146.0
Larnaca	48 705	26.5	15.5	145.0
Limassol	60 004	29.0	21.2	239.1
Pamagusta	76 235	31.6	12.8	117.7
Paphos	44 658	31.4	21.3	183.8
Kyrenia	23,302	30.6	17.2	137.8
(c) <i>Principal Towns</i> —				
Nicosia	26,821	20.9	16.4	55.2
Larnaca	13 170	23.3	19.2	159.6
Limassol	16 610	24.9	22.6	202.6
Pamagusta	11,831	20.7	10.5	122.4
Paphos	4 764	12.8	17.6	147.5
Kyrenia	2,379	43.6	21.9	38.4

A Law to amend the Births and Deaths Registration Law was passed during the year no details are supplied

European Officials resident numbered 110 with an average number resident of 77—one death was recorded during the year. *Of Cypriot Officials* there were 1,836 resident with an average number resident of 1,763. Within this group 6 were invalided and 6 died.

Maternity and Child Welfare Work—In-patients treated for conditions associated with the *puerperal state* numbered 681 with 15 deaths. 169 labour cases were dealt with in the Maternity Wards of the Nicosia Hospital and 4 maternal deaths were recorded. The *training of midwives* was continued under the direction of Dr H. SYMEONIDES. 15 pupils attended the course and all were successful at the local examination. Government Midwives and their pupils attended 363 confinements during the year. *Child Welfare Clinics* continued to function successfully in four of the six principal towns. The work of these clinics steadily increases.

School Hygiene—Satisfactory improvement in the sanitation of schools is reported. The two years course for teachers at the newly established Government Normal School includes lectures in elementary hygiene and physiology and arrangements are being made to supplement lectures by a series of practical health demonstrations. Copies of *Cyprus Public Health* published in three languages, are distributed to all Elementary and Secondary Schools.

During the year under review the services of the five Honorary Dentists were extended to the schools in 465 villages and 16,590 children were examined. In 151 schools visited for the first time a Medical Record Card system was adopted. 9,615 children were examined in these schools and only 1,917 were found to be free from dental defects. It is said that villagers appreciate the dental treatment available for their children, and that the children themselves are willing to have their teeth attended to. Full details of these services are supplied in the *Report on Dental Clinics* contributed by the Honorary Dentist.

Public Health Sanitation etc—The outstanding Public Health experience during the year was the occurrence of the severe epidemic of *cerebrospinal meningitis* to which further reference will be made in a later section of this Summary. Also during 1937 the incidence of *malaria* was somewhat higher than usual. *Anti-malarial work* is very fully described in the *Annual Report of the International Health Division of the Rockefeller Foundation* which appears as an Appendix to the Report under review.

The need for a proper *sewage disposal* system, particularly in the larger towns is said to be more apparent every day. Certain houses provided with small septic tanks lack a satisfactory means of disposing of the effluents from these tanks while there are certain trades and industries which, owing to the absence of sewers find difficulty in getting rid of their waste water etc. The increasing numbers of absorption pits are responsible for considerable soil pollution and are often unable to cope with liquid waste. At the request of the Director of Medical Services Officers of the International Health Division of the Rockefeller Foundation undertook the sanitation of the village of Dheftera in the Nicosia District and installed *bone-hole latrines* in 167 of the 237 houses in the village (with the exception of 70 houses (latrine construction impossible owing to the proximity of wells) each house has its own latrine—the only village in Cyprus of which

this can be said. It is proposed to carry out similar work in other villages. Dr ALLEN of the Near East Foundation was instrumental in obtaining a grant from the Carnegie Trust Fund for *Rural Development* in Cyprus. The scheme is to extend over three years and is to include Agricultural Educational and Health activities in two groups of villages in the Nicosia and Paphos districts. A qualified Sanitary Inspector will supervise simple works of sanitation. Trachoma Nurses and Midwives will also carry out intensive work in the villages concerned. The Government Chemist reports that 103 samples of water were examined and only 69 found to be chemically potable *water supplies*.

As a result of the cerebrospinal meningitis epidemic *housing conditions* were very carefully investigated and reported to be inadequate and unsatisfactory in many places. New legislation is to be enacted to enable the Department to deal with overcrowding and badly ventilated premises. Meanwhile the contribution of the *Mining Companies* to the solution of the housing problem in their respective areas is noteworthy for the Cyprus Mines Corporation and the Tunnel Asbestos Cement Company both embarked upon comprehensive schemes of housing for their labourers and their families. Five trained Sanitary Inspectors employed by the Cyprus Mines Corporation carry out excellent work under the able supervision of the Chief Medical Officer of the Corporation. The Tunnel Asbestos Company has also engaged a trained Sanitary Inspector.

Important legislation—The *Trades and Industries (Regulation) Law* 1937 was enacted during the year. This Law provides for the health and safety of employees in manufacturing plants shops etc. Two Committees have been at work the first enquiring into and submitting recommendations in regard to amenities and health improvements in the Health Resorts in Cyprus while the second has studied the question of nutrition in the Island.

The *School for Sanitary Inspectors* opened in November 1936 with 25 students. In March 1937 nineteen candidates sat for the examination of the Royal Sanitary Institute and eleven were successful among the latter were two Cypriot girls and an officer of the Palestine Public Health Services. Practically every successful candidate found employment.

Port Health Work—To the eight ports of arrival in the Colony 674 steamships and 608 sailing vessels entered during the year the arrivals of 35 aeroplanes were also reported.

Hospitals Dispensaries etc—Work on the new Nicosia Jubilee Hospital makes steady progress and it is expected that the building will be ready for occupation in 1939. At the Larnaca Hospital a new V.D. block a modern Tuberculosis Clinic and a Children's Ward were completed a new operating theatre was erected at the Kyrenia Hospital and additional ward accommodation and an Infant Welfare Centre were provided at the Paphos Hospital. These three hospitals are State-aided institutions. A steady increase in the work of all hospitals is again reported. In Government hospitals further development is restricted by lack of bed accommodation but with the completion of the new Nicosia Hospital this state of affairs should be rectified. The following data have been extracted from a classified statement of the volume of work dealt with during the year —

Institution	Beds and Cots	In-patients	Hospital deaths % of In-patients	" Day-cases (Out patients)"
<i>Government Hospitals —</i>				
Nicosia	107	2,027	8.5	31,793
Limasol	88	762	11.2	13,413
Mental Hospital	—	—	—	—
Leper Farm Hospital	10	57	7.0	—
<i>State-aided Hospitals</i>				
Larnaca	5	968	4.4	14,157
Pamagusta	46	699	3.6	8,186
Paphos	40	633	8.4	9,313
Kyrenia	31	644	2.1	6,829
Sanatorium	53	93	44.0	—
Totals	402	6,238	11.21	83,723

[The conflicting numerical statements appearing in the Report under review make it impossible to understand the actual position in regard to hospital patients treated during 1937. No fewer than four different statements of the numbers of in-patients are given: in the Table quoted above the figure stands at 6,238, in another place 6,584, in another 6,088, and in the classified Returns at the end of the Report it is stated "Admissions 6,421 cases treated 6,595". Furthermore in the Table above 11.21 per cent of the hospital in-patients are said to have died, yet in another classified statement only 398 hospital deaths are recorded. If the 83,723 Day-cases are to be regarded as *Out-patients* then the figure is not in agreement with two other statements which announce that 109,264 and 108,889 out-patients respectively were treated.]

There are 6 *District Dispensaries* one attached to each hospital and 11 *Rural Dispensaries* established in various parts of the Island at these centres 128,186 new and 213,337 old cases were dealt with.

Training of Nurses.—Three Cypriot girls who were sent for a three-year course of training at the American School of Nursing, Beirut, have returned and will be appointed to Government hospitals, a fourth should complete her training in 1938 and four others will commence the course during that year. It is stated that at least 95 per cent of the nurses in Cyprus have had little or no training and that present-day demands make a modern training school for nurses essential. Miss E. CROWELL, Rockefeller Foundation Staff Member in charge of Europe Nursing activities, visited the Island, investigated local conditions and submitted a memorandum on the feasibility of establishing a school of nursing when funds permit.

The notes which follow summarize the principal items of morbidity experience discussed in the Report under review.

With 18,272 reported cases in 1937 the incidence of *malaria* was higher than in the two preceding years. Among the factors responsible for high incidence are mentioned (a) the disorganization of the Medical and Sanitary Services consequent upon the severe epidemic of cerebro-spinal meningitis (see below) and (b) the extensive breeding opportunities created in certain areas caused by delay in emptying the irrigation reservoir and the resultant floods which filled depressions

and river beds. Of the 18,272 cases quoted 728 were treated as in patients with 16 deaths the types of infection being *benign tertian* 584 *quarlan* 42 *subtertian* 84 and *cachexia* 18 and among the 17,544 out patients the corresponding distribution of cases was 11,866 2,911 1,295 and 1,472 respectively. Malaria control work was carried out by the Medical Department and by the Rockefeller Foundation Staff. In an Appendix to the Report under review Dr J C CARTER contributes a comprehensive report under the title of *Annual Report of the Work of the International Health Division of the Rockefeller Foundation in Cyprus 1937*.

At the Government Laboratory where 483 blood films were examined 105 were positive with *P. falciparum* 17 *P. vivax* and 2 *P. malariae*.

The severe epidemic of *meningococcal meningitis* which commenced in the last quarter of 1936 reached its peak during the early months of 1937 continued sporadically well into the early summer and assumed mild epidemic form again during the last three months of the year. It is said that 838 cases were notified isolated and treated, and that 276 terminated fatally. (On p 88 of the Report it is stated 837 cases were notified 280 proved fatal.) Isolation hospitals were established by the Medical Department at a number of centres while in addition the Cyprus Mines Corporation erected two isolation hospitals where they treated not only cases occurring among their own employees and their families but also others from neighbouring areas. The holding of fairs etc which would tend to draw crowds was prohibited under the Quarantine Regulations schools were closed and an extensive educational programme was conducted through the Press and District Administrations. Protective immunization measures on a large scale were instituted. At the Bacteriological Laboratories of St Mary's Hospital London a vaccine was prepared from Near East strains of the meningococcus and during the last three months of the year over 30,000 persons were inoculated. This outbreak and also other epidemics of cerebrospinal meningitis that have occurred in Cyprus from 1878 to 1937 are described in great detail in a special Report contributed by Doctors E A NEFF and C S MARKIDES and presented as an Appendix in the Report under review. This has been exhaustively reviewed in the *Bulletin of Hygiene* 1939 Vol 14 pp 548 to which the reader is referred.

There were 666 cases of *typhoid fever* with 55 deaths and 34 cases of *paratyphoid A* recorded during the year. Maximum seasonal prevalence was reached in August. Kyrenia District showed the highest case incidence but the lowest mortality experience. Lack of proper latrine accommodation and the practice in rural areas of keeping manure heaps in the open thereby providing fertile breeding places for flies are mainly responsible for the disease becoming endemic in the Island. It is said that water supplies though unsatisfactory in many places play but a small part in the transmission of infection. In two villages small epidemics were water borne but the disinfection of the wells put an immediate stop to these outbreaks. The usual routine precautions were taken and T.A.B. inoculations were carried out on a large scale. There were 161 hospital in patient cases with 28 deaths of the total cases 150 were *typhoid* and 11 *paratyphoid A*. Among 180 out patient cases 170 were *typhoid* 7 *paratyphoid A* and in 3 cases the type of infection was not defined.

At the Laboratory where 736 samples of serum were tested 219 agglutinated *Bact. typhosum* 34 *Bact. paratyphosum A* and 82 *Bact. paratyphosum B*

An Appendix to the Report supplies a detailed account of typhoid fever experience during 1937

During the year 84 cases of *dysentery* were notified. Once again it is observed that as the disease shows a preference for children under the age of 5 and that seasonal prevalence is highest in the summer a considerable number of the cases may have been nothing more than ordinary summer *infantile enteritis* (see this *Bulletin* 1938 Supp p 131). Only 12 cases were treated in hospitals and of these 3 were *amoebic* 6 *bacillary* and 1 undefined as to type of infection among 58 out-patients there were 3 *amoebic* cases 34 *bacillary* and 21 undefined. At the Laboratory 144 faecal specimens were examined two were positive with *E. histolytica*.

Considerable progress can be reported in connexion with *tuberculosis* control work. A suitable site for the new Tuberculosis Sanatorium was selected and preliminary plans were prepared actual building work was expected to commence in 1938. Towards the end of 1937 the new Demetrio Tuberculosis Dispensary at Larnaca was ready to deal with patients. Dr A. D. BARDSWELL (see this *Bulletin* 1938 Supp p 131*) assisted by a Government Medical Officer and a trained tuberculosis nurse was to direct the work of the Dispensary and conduct a tuberculosis survey during 1938. Arrangements are also being made to train suitable nurses at the Larnaca Dispensary. The Philip Tuberculosis Dispensary at Nicosia under the direction of Dr T. K. EVANGELIDES continues to develop and extend its work, and it is hoped to establish a dispensary for patients from the Limassol and Paphos Districts. The *Anti-Tuberculosis League* continues to function with success and works in close co-operation with Government Medical Officers.

During the year under review 257 cases of *pulmonary tuberculosis* were notified and 137 of these were female patients. The true incidence of the disease cannot be estimated from these cases, for a certain number escape notification while others are notified owing to errors in diagnosis. Dr BARDSWELL was unable to confirm the diagnosis in 18 out of 224 notified cases. According to Hospital Returns out of 91 in-patient cases of tuberculosis (*all forms*) with 10 deaths, only 14 cases and 1 death were ascribed to the *pulmonary* form of the disease. Among 698 out-patient cases 310 were treated for pulmonary tuberculosis.

In an Appendix to the Report Dr T. Evangelides contributes a detailed account of the year's work carried out at the Philip Dispensary Nicosia and the Athalassa Sanatorium. At the Government Laboratory where 901 specimens of sputum were examined 639 were found to contain *Mycobacterium tuberculosis*.

Eie Clinus—According to the Report new cases treated by the three Travelling Oculists totalled 18 089 (given as 15,885 in another section) and of these 5,556 were *trachoma* cases. Famagusta District heads the list with 4,850 cases which include 2,892 cases of *trachoma*. There are now 18 *Trachoma Nurses* all doing useful work in their respective centres. It is hoped to introduce a Mobile Eye Clinic, an additional full-time Travelling Oculist and more nurses.

The only *helminthic diseases* recorded in the Hospital Returns are 322 cases of *ascariasis* 274 of *oxyuriasis* and 36 of *taeniasis*. It is believed that *schistosomiasis* has practically disappeared no cases were reported nor have snails been readily found in the Island. *Hydatid disease* is said to be prevalent in the cystic form and gives rise to many serious complications. Hospital Returns show that 23 in-patients with 1 death and 34 out patients were treated for hydatid of the liver. During the summer of 1937 an investigation of intestinal parasitism was conducted in some of the insanitary areas of the Island. Among 46 stools of children under 10 years of age 21 contained the ova of *Ascaris* 3 contained *Ascaris* and other parasites 1 *Enterobius*, and 1 *Hymenolepis nana*.

Leprosy.—To the Leper Farm 20 patients were admitted 17 were paroled and 4 died leaving at the end of the year 104 lepers resident.

Venereal Diseases.—In an Appendix to the Report under review Dr N. MICHAELIDES Medical Officer in Charge of V.D. Clinics contributes a survey of the work carried out at the five clinics during 1937. A classified statement shows that 2,242 cases of *gonorrhoea* 1,730 of *syphilis* 268 of *soft chancre* and 188 of other venereal diseases were dealt with. [This makes a total of 4,428 cases, but in another part of this Report it is said 4,252 patients were seen at all centres.] Of the total patients seen 2,638 were new cases. The Laboratory Report states that Wassermann tests were applied to 3,810 samples of serum with positive reactions in 745 cases.

Other diseases.—No case of *smallpox* or *plague* was reported. During the year 12,428 anti-smallpox vaccinations were performed. Anti-rat measures are carried out at all principal ports 2,250 rats were trapped all spleen smears examined at the laboratory gave negative findings. Of *diphtheria* 16 cases with 6 deaths were recorded. Hospital Returns show that 203 in-patient cases of *cancer* with 14 deaths and 241 out-patient cases were treated. In an Appendix Dr C. H. CURT the Surgical Specialist discusses the year's surgical work and among other matters describes the results of seven years of radium therapy for malignant disease the facts are tabulated in detail. The Report under review observes that 1,009 cases of *rheumatism* were dealt with during the year but Hospital Returns show 80 in-patients and 2,640 out-patients a total of 2,720 cases. A widespread epidemic of mild *influenza* occurred during the year hospital in-patients treated for this cause numbered 152 (1 death) and out-patients 6,706.

Scientific.—The Laboratory Report observes that 15,699 specimens were received and examined during the year the principal findings recorded are referred to in the preceding notes. The Government Chemist dealt with 1,462 samples during the year 1,449 of these being received from official sources including foods and drugs water etc. The 12 Special Reports which are presented as Appendices to the Annual Report under review comprise (1) Report of the Surgical Specialist (2) Report of the Cerebrospinal Meningitis Epidemics 1878-1937 (3) Report of the Pathologist (4) Report of the Chemist (5) Report of the International Health Division of the Rockefeller Foundation (6) Report on Social Work (7) Report of the Mental Hospital (8) Communicable Diseases (9) V.D. Clinics, (10) Tuberculosis Dispensary and Athalassa Sanatorium (11) Dental Report (12) Municipal Health Report Limassol.

Financial—Total expenditure on Medical Department services amounted to £60,596 a sum which represents 7·1 per cent. of the total expenditure of the Island during 1937

GIBRALTAR (1937)

Gibraltar consists of a long mountain block (the "Rock") rising to a height of 1,398 feet, 3 miles long and $\frac{1}{2}$ mile broad, joined by a low sandy isthmus to the southern extremity of Spain. The town is built on the western and southern sides of the Rock, facing the Bay of Algeciras the northern and eastern faces are inaccessible cliffs

Introductory—Dr J LOCHHEAD C.B.E. Senior Medical Officer from 1914 to 1937 retired from the Service in October of the year under review and was succeeded by Dr J E DEALE. In his first Annual Report Dr Deale pays a graceful tribute to the long and valuable services of his predecessor who was responsible for so many changes and improvements contributing to the health and welfare of the Colony

Total Statistics—The Police estimate of the resident population at the end of 1937 was 19,541 persons, comprising 16,792 British subjects and 2,749 Aliens. For the ten years previous to 1936 there was an average population of 16,700 persons, and at the end of 1937 the population exceeded the normal average by 18 per cent. The Senior Medical Officer Dr J E Deale observes, the average normal was definitely a saturation figure providing very marked overcrowding amongst the working class population, and it is particularly amongst this latter class that the majority of our present excess population is now housed

Registered births numbered 331 and *deaths* 292, the resulting crude birth and death rates being 19·5 and 14·9 per 1,000 respectively [The Report gives a birth rate of 22·7 per 1,000 but this is obtainable only by relating the registered births to the British population alone the death rate for British subjects reads 15·2 per 1,000]

Infant deaths numbered 26 and the infant mortality rate 68·2 per 1,000 births.

Maternity and Child Welfare Work—To the Maternity Wards of the Colonial Hospital 263 women were admitted of these 203 belonged to the resident population and 60 were British subjects residing in Spain, or Spanish refugees temporarily residing in Gibraltar. Of the 242 hospital births recorded 189 were the babies of resident mothers and 53 those of temporary residents, 14 of the latter being the babies of Spanish women refugees (see this *Bulletin* 1938 Supp. p. 135). At the Colonial Hospital one pupil qualified as a *midwife* and another continued her course of training in midwifery

Fortnightly meetings continued to be held at the *Child Welfare Centre* where an average attendance of 103 was recorded while 239 children were treated in the Children's Ward of the Colonial Hospital.

The Nurse paid 431 home visits during the course of the year and milk and foods were supplied free or at reduced prices in necessitous cases.

School Hygiene—During January April November and December a Nursing Sister paid 24 visits to schools in the Colony and recommended 214 children for medical and 156 for dental treatment. Of the former 73 were suffering from *skin diseases* 58 from *general debility* 28 from *defective vision* 23 from *enlarged tonsils* and 21 from *injuries*. The School Dental Officer treated 665 children for various oral defects and continued his voluntary lectures to school-children at the schools. The Soup Kitchen continued to play an important part in maintaining the nutrition of school-children during the winter months.

Public Health Sanitation etc—The medical and sanitary services of the Colony and those directly administered by the Colonial Government remain as described in previous issues of this *Supplement*. Methods of *sewage and refuse disposal* remain for all practical purposes unchanged (see this *Bulletin* 1934 Supp p 100*). Owing to the closure of the Spanish frontier difficulties were experienced in the disposal of animal manure. Steps were taken for the collection and disposal by dumping in the sea of stable refuse etc. These measures proved highly satisfactory and resulted in almost complete freedom from the fly nuisance.

With regard to *potable water supplies* it is stated that a new reservoir of one million gallons storage capacity is under construction and should be completed in 1938. Substantial renewals to catchment areas were carried out and unproved distribution of supplies to the town was made possible by the provision of larger water mains. *Brackish water* continues to be supplied from wells for purposes other than potable. Public supplies were bacteriologically tested each month and remained free from pollution throughout the year. A constant watch is kept on rain water supplies stored in tanks and liable to be contaminated.

Brief reference has been made to *overcrowding* among the working class population (see *Vital Statistics* above). The recommendations contained in the *Report of the Commission of Inquiry on Housing and Rent Restriction* referred to in the previous issue of this *Supplement* provide the basis upon which the re-housing and abolition of the slums in Gibraltar should be progressively carried out. Plans have already been prepared and schemes drafted for several years work of clearance re-housing etc. and these when completed should provide the working classes with dwellings which should be a model to the world.

The routine inspection of *foods and drinks* was carried out as usual and samples taken for analysis from time to time. Steps were taken to ensure more complete control of *milk supplies and dairies* in the Colony.

Port Health Work—The Board of Health continues to function as the quarantine authority for the Colony and for preventing the introduction of dangerous infections from the Port. During the year 5 828 vessels called and 130 cases of sickness were landed from British and 30 from foreign ships. Rats destroyed during the course of the year numbered 9 763 of these 108 were examined at the Laboratory but all gave negative findings for *P. pestis*.

Hospitals Dispensaries etc—Certain structural improvements and additions were carried out at the Colonial Hospital. The volume of work dealt with at various Government institutions may be set out as follows —

Institution	Admissions	Treated	Died	Out-patients
Colonial Hospital	1 767	1,845	141	12 068
Isolation Hospital	None	3 (leprosy)	2	—
Mental Hospital	7	80	5	—
Home for Sick and Aged	—	58	—	118 Out-door relief

The statistics of the Colonial Hospital were again appreciably influenced by the civil disturbances in Spain, the number of in-patients treated being the highest recorded during the past five years. The notes which follow briefly summarize some of the more extensive commentaries upon principal conditions of sickness treated during the year under review.

The 419 cases of *infectious diseases* recorded during the year included the following. Of *diphtheria* there were 34 cases the majority being of mild type though three more virulent infections resulted in early death. At the Laboratory where a large number of swabs were examined, 35 were new positive cases and *C. diphtheriae* was also isolated in four contact swabs. Four non fatal cases each of *scarlet fever* and *cerebrospinal meningitis* appear in the Hospital Returns. 10 cases of the former and 3 of the latter were notified during the year. An epidemic of *measles* of a mild type commenced in December and up to the end of the year alone 164 cases had been reported with no deaths. the size of the epidemic is a reflection of the overcrowded conditions and the presence of refugees in the Colony. There were also 113 cases of *German measles* recorded and 33 of *chickenpox*.

Twelve cases of *enteric fever* were reported, though Hospital Returns show that 16 cases of typhoid with 1 death, and 1 case of paratyphoid B were treated. The ages of patients ranged between 13 and 27 years. Investigations failed to establish any mutual connexion between cases and on no occasion was infection traced to either milk or water supplies. At the Laboratory of the numerous bloods serologically examined 17 agglutinated *Bact. typhosum* 18 *Bact. paratyphosum B* and 5 *Br. melitensis* (only 1 case of *undulant fever* was recorded).

Three cases of *dysentery* were notified. According to findings recorded at the Laboratory cases were chiefly due to *Bact. dysenteriae* Flexner and Sonne.

Twelve cases of *Fifth disease* (*Erythema infectiosum*) were recorded this disease had not previously been recorded in the Colony though it is thought that occasional cases may in the past, have escaped recognition. As a clinical entity the disease is said to be well established and it has been considered desirable to make it officially notifiable.

No case of *smallpox* was notified. 406 primary and 302 revaccinations were performed during the year.

Thirty four cases of *pulmonary tuberculosis* were reported and 21 deaths were ascribed to this cause during 1937. The Tuberculosis

Officer appointed in 1936 (see this *Bulletin* 1936 Supp., p 136*) appends a detailed report of his work. Towards the end of 1936 Government decided to embark upon an active anti tuberculosis campaign allotted funds to start a *Tuberculosis Dispensary* and decided to build a *Sanatorium* the building is well in hand and it is hoped it will be brought into use in 1939. At the Dispensary 44 sessions were held with an average attendance of 7 and 58 new cases were seen. At the Laboratory where 178 specimens of sputum were examined, 25 per cent were positive with *Mycobacterium tuberculosis*. The bacillus was not found in samples of cows' milk taken at regular intervals throughout the year.

The *Veneral Diseases Clinic* at the Colonial Hospital is reported to have dealt with 30 cases 13 of these being mercantile seamen. Hospital Returns of in patients show 12 cases of *syphilis* 2 of *soft chancre* and 22 of *gonococcal infections*. The usual examinations of blood for Wassermann or Kahn reactions and of smears and urine for gonococci were carried out. 75 out of 565 samples were Wassermann positive and gonococci were found in 25 out of 131 smears examined.

Though mosquito and other insect borne diseases are not endemic in the Colony (see this *Bulletin* 1937 Supp. p 128*) men are permanently employed on mosquito destruction throughout the year with additional workers during the summer months. Three cases of *malaria* were landed from British and 4 from foreign ships while among Hospital in patients 8 were suffering from the disease. Blood films of 23 patients were examined at the Laboratory and 7 were found to contain *malaria* parasites.

One case of *rabies* in a cat was discovered and the man scratched by the animal given a full course of treatment at the Colonial Hospital.

Scientific—An up-to-date *Public Health Laboratory* is maintained by the City Council an Abstract of the Annual Report of the Laboratory is contributed by Mr A G HOLBOROW F.I.C. City Analyst and Bacteriologist and included in the Report under review. During the year 5,344 specimens were examined and reported upon and of this total 1,367 were examined on behalf of the Colonial Hospital. The principal specimens examined and findings recorded have been the subject of brief mention in the preceding notes.

During 1937 a *Government Veterinary Officer* was appointed consequent upon the withdrawal of the Military Veterinary Surgeon. A Veterinary Section is included in the Report under review and in it are discussed veterinary activities of Public Health importance.

Financial—Expenditure from Government funds upon Medical and Sanitary Services during 1937 amounted to £24,338 a sum which represents 11.7 per cent. of the revenue of the Colony during the same year.

MALTESE ISLANDS (1937)

The Maltese Islands, a group of islands in the Mediterranean Sea, are distant about 53 miles from the nearest point of Sicily 80 from Syracuse 142 from Reggio and 180 from the nearest point of the mainland of Africa. Malta itself is 17 miles long 9 broad and has an area of almost 95 sq miles. Gozo 28 sq miles. Comino and Filfa are mere islets, the area of the former being about 1 sq mile. The whole group has about half the area of the Isle of Man.

vital Statistics—The recorded facts continue to be presented in admirable detail. The following brief summary supplies the fundamental items—

Item	Malta	Gozo	Both Islands
Estimated Population	233 970	25 693	264 663
Registered births	8,508	673	8,879
Birth rate per 1 000	34.3	26.2	33.5
Registered deaths	4,830	474	5,304
Death rate per 1 000	20.2	18.4	20.0
Infant deaths	1,983	170	2,153
Infant Mortality per 1 000 live births	241.9	252.6	242.7

A high birth rate is steadily maintained but the infant mortality rate continues to be excessive. The increase in infant deaths during 1937 was due to a higher incidence of diarrhoea and enteritis which was responsible for 64.4 per cent of the total infant deaths due to all causes.

Maternity and Child Welfare Work—To the Maternity Wards of the Central Hospital 427 women were admitted and 390 deliveries with 25 maternal deaths were recorded. Out of a total of 403 babies resulting from the deliveries 298 were born alive and 105 were stillborn. To the Gynaecological Department of the same hospital 408 patients were admitted and 5 died. Ante-natal consultations are held in the Out Patient Department and during the year 2,080 cases were dealt with. District Nurses of the Medical Department visited all newly confined mothers where this service is available. During the year 5 433 such visits were paid in Malta and 1,064 in Gozo. Free midwifery assistance was granted to 901 mothers during the year. Subsidies were given to two midwives, enabling them to reside within reach of outlying villages. Money grants were made to necessitous mothers with babies under one year of age.

Government continued its support to the Mothers and Infants Health Association which maintains four baby welfare centres and performs splendid work among newly confined mothers and their infants.

Sixty-eight cases of *puerperal sepsis* with 13 deaths were notified during the year.

The training of nurses and midwives is discussed in the section "Hospitals" hereafter.

School Hygiene—The School Medical Staff consists of two part time Medical Officers: one a specialist in ophthalmology (see *trachoma* below)

and the other a Lady Doctor who will become a whole time Officer in 1938. During the year under review 21,231 children were examined in Malta and 3,293 in Gozo. *Trachoma* is the disease to which the attention of school medical officers is specially directed. 297 cases were found in Malta schools and 345 in Gozo. The *nutrition* of school children receives careful consideration: a free milk ration is given daily to 5,600 children in Malta and it is hoped to provide similar free issues to the Gozo children. Dental caries, enlarged tonsils and adenoids were other conditions reported during the inspections of school-children. Daily lectures on hygiene and home nursing were given to the girls in senior classes at the Housecraft School, and weekly lectures to the pupils at the Central School, but it is desirable that the teaching of elementary hygiene should be extended to all schools.

Public Health Sanitation etc.—The Annual Report for 1937 contributed by Dr V. V. BERNARD, Chief Government Medical Officer, provides an interesting and informative review of the state of the public health, the work of the Public Health Department and of those branches of the Charitable Institution Department which were amalgamated to form the newly created *Medical and Health Department*. These new developments call for brief mention.

In 1936 the merging of the medical and health activities of the Government (at that time two separate departments) under central control was recommended as desirable and Sir Walter JOHNSON, formerly Director of Medical Services, Nigeria, was nominated by the Secretary of State to investigate and report upon the system of Medical and Public Health Administration in the Maltese Islands. The enquiry was carried out during the early part of 1937 and in addition to supporting strongly the proposals for amalgamation of the two departments, Sir Walter JOHNSON made several suggestions for the expansion of other Governmental medical and health activities. The *Medical and Health Department* came into being on the 1st November 1937 and was placed under the control of the chief Government Medical Officer to whom also were transferred the powers and duties formerly exercised by the Comptroller of Charitable Institutions. The newly created department now controls land and port health services, laboratories, hospitals and asylums, district medical services, poor relief, etc.

The importance of providing proper systems of *sewage disposal* is again emphasized (see this *Bulletin* 1938 Supp. p. 138*) during the year the sewers were extended in several towns and villages. The newly organized system for the collection and disposal of *refuse* commenced to function and is gradually being extended. Restrictions of *water supplies*, a consequence of deficient rainfall, again became necessary: additional supplies from a new source became available and the extension of old storage galleries was continued. A section of the Report discusses *housing* in some detail and contains matter of historic interest concerning the efforts directed towards housing reform in Malta from the middle of the 19th century to the present time. The routine inspections of *foods and drinks*, their manufacture and sale, etc., were continued by Sanitary Inspectors.

The Report contains a large number of Appendices and special reports containing medico-statistical statements and descriptive accounts of the various health and medical activities.

Port Health Work.—The title of Quarantine Medical Officers was changed to Port Medical Officers during the year. Rat plague was reported in countries within a few hours' journey of Malta and from which merchandise liable to carry rats or fleas is imported in large quantities. The services of the newly appointed Port Sanitary Inspector proved especially valuable in ensuring efficient watch over the condition of such merchandise, and in connexion with the inspection of wharves, warehouses, deratization, rat proofing, etc. The intensive anti-rat campaign continued (see this *Bulletin* 1938 Supp. p. 139*). During the year 2,118 steam and 399 sailing vessels entered Maltese ports, and the arrivals of 9 British and 205 foreign aircraft were recorded.

Hospitals, Dispensaries, etc.—Considerable space is devoted to the discussion of Hospitals and Institutions, and in this section Dr. Bernard contributes interesting historical notes describing the origins and subsequent development of the various hospitals and charitable institutions in Malta and Gozo. The following summary statement relates to the institutions now under the control of the Medical and Health Department, and the volume of work dealt with during the year under review.—

Institution	Admissions	Treated	Died
<i>Malta</i>			
Central Hospital	5,297	5,552	424
Santo Spirito Hospital	287	342	16
Connaught Hospital for T.B.	138	246	51
Mental Diseases Hospital	243	1,031	48
Isolation Hospital	500	521	48
Leprosy Hospital	16	93	6
Foundling Hospital	?	?	?
Hospital for Incurables and Poor	834	1,013	21
Magdalen Asylum	?	?	?
Orphan Asylum	8	110	0
<i>Gozo</i>			
Victoria Hospital	903	979	31
St. Teresa Hospital for T.B.	6	23	5
Mental Diseases Hospital	35	222	13
Isolation Hospital	52	37	1
Leprosy Hospital	15	—	—
Gozo (Aged and Invalid Poor)	37	193	31

The District Medical Service is organized on the basis of 26 districts in Malta and 5 in Gozo for purposes of medical and sanitary administration. A Medical Officer is allotted to each district (except in Valetta District where there are 2) and in practically every town or village is a dispensary. Poor patients are treated free of charge at these centres and at their homes by district medical officers, who also function as Medical Officers of Health within their respective districts. During the year under review district medical officers paid 116,091 visits to 34 dispensaries in Malta for the treatment of poor patients, and made 43,641 day and 2,088 night visits to the homes of poor patients. In Gozo 11,793 visits were recorded at 12 dispensaries and 2,328 day and 193 night visits to the homes of patients were paid.

With regard to the training of *Nurses and Midwives* and other Hospital personnel it is reported that the scheme for the establishment of a nursing School in Malta was further developed. An English trained nurse was appointed as Sister Tutor and with her assistance 12 candidates were selected for later training in England and she also started a refresher course for the Sisters at the Central Hospital. A course for Hospital Attendants was started at the Central Hospital and a similar course at the Victoria Hospital Gozo. As no candidates attended the course of *Midwifery* held in Malta, a course was started at the Victoria Hospital, Gozo in October.

A number of *Charitable Institutions* in Malta and Gozo are subsidized by Government and a number of Religious Houses and private charitable organizations are supplied with medicines free of charge.

Twenty-six diseases are compulsorily notifiable. For seven of the scheduled titles no cases were reported but for the remaining nineteen 2,972 cases with 433 deaths were recorded. The principal diseases commented upon in the Report under review include those briefly discussed in the notes which follow.

The year saw the cessation of the 1936 outbreak of *plague* (see this *Bulletin* 1936 Supp. p. 138*). Six cases with one death were notified in January 1937 one fatal case in April, and another in May. Spleen and liver smears from 13 410 rats were examined at the Laboratory and 5 found to be infected with *P. pestis*. The intensive campaign against rats is to be continued for though no plague-infected rat was discovered after May 1937 it was considered prudent to ensure that no relaxation of anti-rat measures should take place.

No case of *smallpox* was reported. District Medical Officers performed 4 440 vaccinations during the year and 92 per cent. were reported as successful.

One hundred and twenty cases of *diphtheria* with 23 deaths were recorded, 94 of the cases and 21 of the deaths occurring among children under 5 years of age. *Measles* was responsible for 8 non fatal cases only *whooping cough* 314 cases with 11 deaths, *influenza* 300 cases and 24 deaths and *scarlet fever* 22 non fatal cases.

Of *enteric fever* there were 168 cases and 27 deaths were ascribed to this cause only 4 (non-fatal) cases were reported from Gozo.

The incidence of *undulant fever* increased from 873 cases in 1936 to 1 034 cases in 1937 and deaths from 52 to 60 in the latter year. The Milk Pasteurization plant has been brought into use making available milk of guaranteed purity which is already very popular. It is intended to prohibit the sale of raw milk from centres which can be supplied by Government milk this step will see the removal of milch goats from the streets. The *Undulant Fever Research Station* continued its activities principally directed towards the investigation of the variations of *Br. melitensis* blood and milk serum agglutination tests etc. (see also this *Bulletin* 1938, Supp. p. 140* and *Bulletin of Hygiene* 1939 Vol. 14 p. 625).

Notified cases of *pulmonary tuberculosis* numbered 210 and deaths 123. The need for a co-ordinated scheme for the control of the disease is again referred to (see this *Bulletin* 1938 Supp. p. 140*). There are at present two hospitals for tuberculosis and District Medical Officers deal with out patient cases. Other respiratory

affections mentioned include *broncho-pneumonia* 207 cases, 103 deaths and *pneumonia* 112 cases with 29 deaths.

The arrangements previously made for the discovery and treatment of cases of *trachoma* were continued (see this *Bulletin* 1939, Supp. p. 140*). During the year 176 new infections were recorded in Malta and 64 in Gozo while "old" cases under treatment in these two islands were 539 and 500 respectively. Efforts are especially directed towards the detection of cases among school-children, and intensive treatment by School Medical Officers. During 1937 there were found 297 cases in Malta schools and 345 in Gozo schools. At the Ophthalmic Clinic of the Central Hospital, Malta 691 cases of the disease were treated.

Leprosy—Here again Dr. Bernard supplies a most interesting historical account of early efforts directed towards the care of lepers from the 14th century onwards. Mention has been made in the classified returns under the heading *Hospitals* above of the patients treated at the Leprosy Hospitals in Malta and Gozo. As regards the institution in the latter island, this was opened in December 1937 for the isolation of lepers in Gozo.

Veneral diseases—The Report of the Medical Officer in charge of the Venereal and Dermatological Department of the Central Hospital, Malta, observes that 36 in-patients and 230 out-patients were dealt with in the venereal diseases section during the year. Among the in-patients were 13 cases of *syphilis*, 22 of *gonorrhoea* and 1 of *condylomata*; and among out-patients 33 new and 78 old cases of *syphilis*, 81 new and 29 old cases of *gonorrhoea* and 9 cases of other V.D. This Report classifies cases in a series of Tables showing age, sex, disease, source of infection, occupations of patients, etc. together with details of drugs and treatments in use.

Scientific—Presented as Appendices to the Report under review are the *Public Health Laboratory Report* and the record of the year's work carried out at the *Clinical Laboratory of the Central Hospital, Malta*.

At the Public Health Laboratory 24,692 samples and specimens were dealt with. The principal findings recorded are presented in a series of Tables and discussed in the text of the Report. District Medical Officers and Private Practitioners submitted 4,240 samples of human blood for the serological diagnosis of undulant fever and enteric fever, 1,069 agglutinated *Br. melitensis* and 96 *Bact. typhosum*.

At the Central Hospital Laboratory 10,347 specimens were received and examined. The number and nature of different specimens examined and findings recorded are classified. Among them were 3,012 specimens of blood serum and of these 91 agglutinated *Bact. typhosum* and 147 *Br. melitensis*.

A Clinical Laboratory is also established at the Victoria Hospital, Gozo. During the year 1,517 specimens were dealt with, but findings are not recorded.

Financial—The financial year covers the period April 1937 to March 1938. Total expenditure on Medical and Health Services amounted to £221 14s.

INDIAN OCEAN

CEYLON (1937)

Ceylon, an island in the Indian Ocean, lying off the southerly extremity of India, has an area of 25 332 sq miles exclusive of the Jaffna lagoon, the area of which is 149 sq miles. Colombo, on the west coast, is the capital. Its greatest length is 270 miles from north to south, and its greatest width is 140 miles. The total area is rather more than three fourths that of Ireland.

Vital Statistics—The relevant facts may be tabulated as follows —

Races and Communities	Estimated Population	Births	Birth Rate	Deaths	Death Rate	Infant Deaths	I.M.R.
Ceylonese	5 043 000	190 487	37.7	111 656	22.1	29,855	157
Europeans	10 000	87	9.7	63	6.3	4	41
Indians†	654 000	25 493	38.4	12 691	19.0	4 321	169
Totals	5 712,000	216 079	37.8	124 210	21.7	34 180	158

†Immigrant population on estates. [The total is elsewhere given as 664 000.]

The North-Central Province again shows the highest birth death and infant mortality rates and the Western Province the lowest birth rate and the second lowest death and infant mortality rates in the Island.

The *vital statistics of urban (37 towns) and rural areas* are presented in the following detail —

Area	Estimated Population	Birth Rates	Death Rates	Death Rates per 1 000 live births	
				Maternal	Infant
<i>Urban Areas</i>					
(a) Residents and non residents	799 000	39.7	31.6	31.6	168
(b) Residents only	—	27.8	20.3	—	162
<i>Rural Areas</i>	4 913 000	37.5	20.0	17.9	157

It is again noted that in rural areas the causes of death reported cannot be regarded as reliable (see this *Bulletin* 1937 Supp. pp 134*–135*). In the 37 principal towns where the majority of deaths are certified as to cause by medical practitioners among 25 770 deaths registered *infant deaths* were responsible for 20.7 per cent, *pneumonia* 14.9 per cent, *malaria* 5.9 per cent and *pulmonary tuberculosis* for 5.2 per cent of the total.

Maternity and Child Welfare Work—This was carried out at 207 centres as compared with 77 in the preceding year. During the year under review 8,395 clinics were held and attendances by expectant mothers were 39,841 by infants 88,479 and by children of pre-school age 39,637. Infant mortality and maternal mortality rates for the Island as a whole show reduction by comparison with 1936 experience though *puerperal sepsis* and *puerperal convulsions* continue to be serious causes of maternal mortality, and in 1937 were responsible for 78.4 per cent. of the total deaths at childbirth.

At the *ante-natal clinics* held at the *De Soysa Lying-in Home* 7 942 mothers paid 11 196 visits and at the *post-natal clinics* 487 mothers paid 1 042 visits. At this Lying-in Home maternity bed accommodation was increased from 107 to 130 and 78 *Government Hospitals* had maternity wards with bed accommodation for 501 patients. A new maternity ward with 6 beds was built at Chavakachcheri Hospital other hospitals lacking maternity wards take maternity cases into their general wards.

Lady Doctors are stationed at 5 centres for work among women and children, chiefly of the Muslim population. During the year these Lady Doctors paid 3 755 home visits attended 391 mothers at child birth 479 puerperal cases, 1,859 sick expectant mothers 2,972 sick infants and 6,377 sick children of pre-school age they held also 841 clinics at 18 centres.

Registered midwives in the Island numbered 785 as against 524 in 1936. There are 225 trained midwives under supervision provided by Government. The *training of midwives* was continued at the four established centres (see this *Bulletin* 1937 Supp. p. 135*) where 61 pupils were under instruction. There are also 41 *Public Health Nurses* employed at various centres.

The *Voluntary Associations* engaged in carrying out child-welfare work increased from 48 to 60 contributions to the finances of these associations were made by 33 local authorities.

Among the *Indian population on Estates* the infant mortality rate was 169 and the maternal mortality rate 18.2 per 1 000 births. *Debility prematurity and convulsions* were the chief causes of infant mortality and of the 464 deaths of Indian mothers, 195 were due to *puerperal sepsis* principally caused by dirt and faulty midwifery.

School Hygiene—A good deal of attention is devoted to the health of school-children the staff engaged on this work comprises 81 medical officers (of whom 8 are whole time) and 9 school nurses. During the year 773 primary schools, 1,800 secondary 15 collegiate and 1 training school were visited and a total of 84 730 pupils medically examined. 66.1 per cent. of the pupils showed defects of one kind or another with an average of 2.2 defects per defective pupil. The principal defects recorded were *hookworm* 19.1 per cent., *teeth and gums* 13.6 per cent., *malnutrition* 9.7 per cent., *anaemia* 8.3 per cent., *pediculosis* (chiefly among girls) 7.5 per cent., *tonsils and adenoids* 7.3 per cent. necessary treatments were given for the correction of defects.

Special spleen and parasite surveys were carried out in selected areas where 100 children below the age of 12 were selected from schools in each of the areas and blood films taken from them every month from July onwards. The annual spleen survey of boys was carried out in March 138,776 boys were examined and gave an average spleen rate of 28.3. Work concerned with quinine administration hookworm treatment T.A.B. inoculation anti-smallpox vaccination etc. continued to be carried out along lines previously described.

Interest in *school health education* continues to be maintained and during the year 52 teachers were awarded the joint certificate of the Education and Medical Departments granted for passing the examination held after completion of the training course.

Public Health Sanitation etc.—Public health work is reported to continue to make steady progress. The *Malaria Control and Health*

Scheme inaugurated in 1936 and applied to defined areas was extended to include numerous other areas in 1937. Considerable prominence is devoted in the Report under review to describing in great detail the various aspects of the work carried out during the year. No attempt can be made in the present summary to condense the comprehensive accounts presented of areas and populations dealt with special anti malaria measures investigations and surveys constructions undertaken by the Division of Sanitary Engineering etc. for a full account of these matters the reader is referred to the Report itself.

Special attention is paid to matters concerning *sewage disposal* and the control of soil pollution. At present the most popular method of disposal of night-soil is by trenching but disposal by incineration and composting are among other methods adopted in certain areas. During the year 21 792 latrines were constructed this total includes 4 672 bucket latrines in urban areas and 16 169 deep pit latrines in rural areas. Methods of *refuse disposal* remain as previously described (see this *Bulletin* 1938 Supp. p. 143*) further supplies of dust-bins were supplied for use in Urban District and Sanitary Board towns and in some rural areas.

The provision of protected *water supplies* receives the careful consideration of the authorities and during the year 291 new public and 4,215 new private wells were constructed while improvements to 2 794 existing wells were carried out. Investigations soil surveys and borings were undertaken in connexion with proposed water supplies schemes by the Division of Sanitary Engineering. Inspections of town supplies were regularly carried out and samples of water taken for bacteriological and chemical analyses.

Housing in Urban and Sanitary Board areas is controlled and in such areas small housing schemes have been carried out. In rural areas where peasant colonization schemes are being implemented, the dwellings of settlers are constructed in accordance with type plans supplied by the Medical Department. Regular inspection of labourers lines on estates are carried out. Appreciable activity is reported in connexion with the construction and improvement of lines for the housing of labour.

Eleven Health Units continued to function throughout the year under review though no new areas were opened up existing health unit areas were extended in two cases. These areas aggregate 1,378 square miles with a total population of 898,381. The total personnel employed during the year included 11 Medical Officers of Health 5 Medical and 4 Field Medical Officers 92 Sanitary Assistants 30 Public Health Nurses, and 143 Midwives. Work continued along lines previously described (see this *Bulletin* 1938 Supp. p. 144*) and is reported to have been satisfactory in every respect.

Two *training classes for Sanitary Assistants* were conducted 40 candidates were enrolled in the first course, 36 took the final examination of the Royal Sanitary Institute and 29 were successful, while the corresponding figures for the second training course were 46 41 and 31 respectively. Two training classes were also conducted for *Public Health Nurses* at the Kalutara Totamune Health Unit.

Port Health Work (see also this *Bulletin* 1937 Supp. p. 137*) — During the year 2,788 steam and 203 sailing vessels entered the Port of Colombo and of these 44 arrived with 65 cases of infectious diseases.

7 cases were handed to the Infectious Diseases Hospital the remainder being isolated on board the ships concerned. At the 15 minor ports 579 steam and 2,391 sailing vessels called. Twenty seven cases of *Anthrax* plague were recorded in Colombo special measures have now been taken to guard against the introduction of the infection from plague infected ports.

Altogether 101 951 persons passed through the *Mandapam Quarantine Camp* in 1937 and of the total 51 427 were estate labourers the increase is attributed to the rise in the price of rubber and tea occasioning demands for additional labour. Fifty-one passengers and 49 estate labourers were rejected on account of leprosy and 5 estate labourers rejected for other diseases. 36,832 passengers and 50,943 estate labourers were vaccinated against smallpox and 42 182 labourers were treated for ankylostomiasis. At the *Talaparam Quarantine Camp* where 60 601 passengers from India were dealt with 216 were rejected, 183 of these for leprosy. During the year also 98 per cent. of the persons entering Ceylon under surveillance from Southern India reported at their destinations and completed their period of 12 days surveillance.

Hospitals Dispensaries etc—With a view to relieving the acute overcrowding of patients at certain hospitals wards of light construction each containing 32 beds were built for use in six hospitals and the provision of a further five such wards has been budgeted for in the 1937-38 estimates. Five Cottage Hospitals, each of 14 beds, are in course of construction in remote rural areas adjoining suitable central dispensaries six additional hospitals of the same type are to be erected.

The relevant facts relating to hospital accommodation and the volume of work dealt with during the year may be summarized as follows —

Province	(Number of Hospitals)	Number of Beds	Patients Admitted	Patients Treated	Hospital Deaths
Western	24	5 581	101 887	106 066	7,294
Central	23	1,807	89 316	80,009	3 065
Southern	11	662	42,336	42,532	2,496
Northern	12	642	17 317	17 699	665
Eastern	6	457	9,857	10,303	457
N. Western	6	672	31 136	32 106	2,411
N. Central	4	210	8 643	8,904	509
Uva	12	700	22,675	23 218	901
Sabragamuwa	13	1 045	40,561	41 604	1,575
Totals	114	12,046	332,948	343 442	19 723

In addition to the above general hospitals the *Prison Hospitals* (12 Prisons, Hospital bed accommodation in 9) having a total of 333 beds, 5 130 in-patients were treated with 32 deaths, and 73 348 out-patients were dealt with. At the *Lunatic Asylum* 3,942 patients were treated 881 were discharged and 281 died, while at the *House of Observation* (uncertified persons) the corresponding figures were 2,755 1 182, and 81 respectively. At the two *Leprosy Asylums* 1 166 patients received treatment, 100 were discharged and 79 died.

Central and branch *dispensaries* and visiting stations maintained by Government totalled 665 (an increase of 14) and in addition special

institutions are maintained for the treatment of *tuberculosis eye diseases* etc. At the dispensaries and out patient departments of Government hospitals 5 895 649 patients paid 8,872,871 visits for treatments *malaria helminthic diseases gastro-intestinal affections skin diseases* and ulcers were among the principal ailments dealt with. Hospitals maintained on *estates* numbered 92 (an increase of 7) and dispensaries 723 (a decrease of 10). The work at the chief Colombo and outstation hospitals is described in some detail briefly summarized the principal facts read as follows —

Hospitals etc in Colombo
General Hospital—In patients 32,373 deaths 2,755 out patients 323 Out-patient Clinic Diseases of Women new patients 1 620
 Nose and Throat Dept 10 138 new out patients Pathological Dept examined and reported upon 82,546 specimens
Dental Institute—25 198 new patients treated
De Soysa Lying in Home—10 736 in patients 6 124 live births 387 infant deaths, 180 maternal deaths Chief training school for midwives.
Victoria Memorial Eye Hospital—3 207 in patients admitted 29 967 new out patients the School Clinics dealt with 463 children.
Lady Havelock Hospital for Women and Lady Ridgeway Hospital for Children—In patients women 2,345 children 3 660 deaths of women 101 and of children 818. In the training school for Nurses 58 pupils
Female I D Hospital—In patients 428 no deaths out patients 35 501
Infectious Diseases Hospital—In patients 3 023 deaths 214

Outstation Hospitals

Kandy Hospital—Patients admitted 15 992 *Eye Institute*—1 692 in patients 12,820 out patients. Kandy Hospital is a training school for nurses 48 pupils were undergoing training during 1937
Galle Hospital—In patients 16,262, deaths 934 The Hospital is also a training school for nurses In the Eye Institute 10 907 cases were treated.

The training of nurses and midwives is undertaken at various hospitals (see above) but it is stated that the supply of trained nurses falls far short of the demand with the result that nursing staffs at many hospitals are below strength. The Training School in the New Nurses House will be started when the second stage of the building programme is completed (see this *Bulletin* 1938 Supp p 146*)

The notes which follow briefly summarize the principal items of morbidity experience commented upon at greater length in the Report under review

Malaria remains the most outstanding cause of sickness in the Island and during 1937 was responsible for 16.6 per cent of the total number of in patients treated in hospitals for all causes and for 38 per cent. of the cases dealt with as out patients at hospitals and dispensaries. The records show that by comparison with 1936 experience fewer cases were treated and deaths recorded the figures being in-patients admitted 55 755 treated 57 135 hospital deaths 1 448 and out patients treated at hospitals and dispensaries 2,251 786 Deaths due to malaria in the Island as a whole numbered 4 405 and in addition 13,918 deaths were assigned to the title *pyrexia* (unspecified)

The distribution of types of infection among the 57 135 in patients was *benign tertian* 49,311 *quartan* 1 053 *subtertian* 697 *cerebral malaria* 711 and *cachexia* 5,363

In addition to the above there were 55 cases of *blackwater fever* with 3 deaths Brief reference has already been made in the section *Public*

Health above and in previous issues of this Supplement to the extensive anti-malarial work carried out in the Island.

There were recorded 29 cases of *plague* with 28 deaths. 27 of the cases and 27 of the deaths were reported in the City of Colombo where there was a rat epizootic and 48 infected rats were detected. The usual anti plague measures continued to be energetically carried out. The Report of the Division of Medical Entomology supplies an account of rat flea surveys carried out in various areas and of the results obtained. During the course of the year 4 402 rat fleas were received at the laboratory and identified. In the areas surveyed collections of *Y. cheopis* accounted for proportions ranging between 52.4-62.8 per cent. of the total flea catch.

No cases of *cholera* were recorded during the year and only two (non fatal) cases of *smallpox*. Both of these cases (one an American and the other an Englishman) which were of the confluent type had been vaccinated prior to onset of the disease. Primary vaccinations performed during the year numbered 162,826 and of these 88 per cent. were successful.

Diphtheria was responsible for 135 cases and of these 96 cases were treated in hospitals with 22 deaths. In the Island as a whole 34 deaths were ascribed to this cause. Cases of *influenza* treated at dispensaries totalled 295 767 while hospital in-patient cases numbered 11 757 with 141 deaths. Deaths in the Island due to this cause numbered 2,067 making influenza the seventh most important cause of death during the year under review. *Measles* gave rise to 7,248 cases and 26 deaths, *chickenpox* 6 137 cases and 2 deaths, *whooping cough* 2,242 cases with 6 deaths, and *whooping cough* 662 cases with 8 deaths.

Notified cases and deaths due to *enteric fever* numbered 2 629 and 502 respectively yet 3,278 in-patient cases were treated in hospitals (3 137 being admissions during 1937) and 715 died. Of the hospital cases 2 582 were *Bact. typhosum* infections, 130 were *Bact. paratyphosum A*, 6 were *Bact. paratyphosum B* and in 560 cases the type of infection was not defined. It is said that the actual prevalence of the disease cannot be assessed from hospital records since many cases resort to ayurvedic treatment and the majority of cases probably are not notified. At the *Bacteriological Institute* where 14 696 samples of blood serum were examined 1,900 were positive with *Bact. typhosum*, H and 300 with O agglutinins, 114 with *Bact. paratyphosum A* " H and 30 with O and 283 with *Bact. paratyphosum B* H and 62 with O agglutinins.

As regards *dysentery* though only 3 711 cases and 367 deaths were notified to the Sanitary Branch, 6 037 cases were treated in hospitals (5,874 admitted during 1937) with 728 deaths. Of the hospital in-patient cases 3 093 were defined as *amoebic*, 1,564 as *bacillary* and in 1,380 cases the type of infection was not defined. These figures however are not of great value since the distinction was often made on clinical grounds only. It is added that among the small number of cases submitted to complete laboratory investigation the bacillary type greatly preponderated. The Laboratory Report shows that among 2,338 faecal specimens examined 207 were positive for *Bact. dysenteriae* and *amoebae* while 22 out of 260 specimens were positive for *E. histolytica* only.

It is to be noted that in addition to in-patient cases 27,399 out-patients received treatment for dysentery during 1937

For *tuberculosis* (all forms) 6,452 persons were treated as in-patients at Government hospitals and 1,286 died of these totals no less than 4,554 cases and 1,169 deaths were ascribed to the *pulmonary* form of the disease. At outdoor dispensaries 2,494 patients were treated. The four special institutions maintained for the treatment of pulmonary tuberculosis are—the *Anti Tuberculosis Institute* Colombo (Outdoor) *Kandana Sanatorium* Western Province the *Kankasanturai Sanatorium* Northern Province for early cases and the *Ragama Tuberculosis Hospital* Western Province for moderately advanced cases. At these institutions 1,714 in-patients were treated, 407 died and there were 3,696 out-patients. In the Island as a whole 3,145 deaths were ascribed to pulmonary tuberculosis in 1937. *Pneumonia* caused the deaths of 11,008 persons in Ceylon during the year under review. Hospital cases of the disease numbered 8,739 with 2,985 deaths; there were also 4,644 in-patient cases of *broncho-pneumonia* with 1,285 deaths and 8,446 cases of *bronchitis* with 358 deaths.

Leprosy—During the course of the year surveys were carried out in selected areas in four Provinces and in addition 30,411 children were examined in 208 schools when 16 cases were detected. Fifteen treatment centres were operating during the year in the Western, Eastern and Southern Provinces and at these Clinics there were 440 cases under treatment and 552 under observation. At Government Hospitals 1,292 in-patient cases were treated with 84 deaths. Comprehensive reports describe the year's work at the two Leper Asylums in the Island and from these reports the following data have been extracted—

Leper Asylum	Admitted	Treated	Discharged	Died
Mantova	57	242	21	13
Hendala —				
Ceylonese	129	792	39	53
Indians	30	132	40	11

At the Laboratory where 9 smears were examined only 1 was positive with *Mycobacterium leprae*.

Helminthic Diseases—In the Island as a whole 1,708 deaths were ascribed to *ankylostomiasis* and 3,502 to other intestinal parasites during 1937. The Hookworm Campaign was more intensively conducted and the following treatments recorded—

At Government Institutions	1,443,893
At outside Institutions	30,483
By Campaign Staffs	488,329
Health Units	62,150
Mandapam Camp	42,182
Estate Medical Staffs	96,336
Total	2,163,373

Hospital Returns show that 15,733 in-patients were treated for *ankylostomiasis* and that 462 hospital deaths were assigned to this

cause. Among hospital records also appear 3 168 cases of *ascariasis* with 266 deaths.

An Island survey of *filaria*s was undertaken. Work commenced in April and by the end of the year the whole of the North Western Province and the Hambantota District of the Southern Province had been surveyed. Results are described in some detail but limits of space prohibit their repetition in these pages. It was noted that 34 per cent of the blood films examined in one area were positive for *Microfilaria malaya* as the water plant *Pistia stratiotes* is held responsible for the propagation of the intermediate mosquito hosts, steps are being taken for the removal of the *Pistia* plant throughout the Island. This survey work continues. During the year 134 cases of filarial diseases were admitted to hospitals 2 died and there were also 96 out patient cases.

Venereal Diseases.—In patients treated at the various hospitals numbered 7 675 (with 81 deaths) and out patients 31,871. The distribution of infections among in-patient cases shows 2,382 cases of *syphilis* 296 of *soft chancre* and 5 027 of *gonococcal infections*. At the five special V.D. Clinics cases dealt with were as follows —

Clinic	Syphilis	Gonorrhoea	Other V.D.	Yaws
Colombo —				
General Hospital	1,333	3 171	18†	—
Fort Clinic for Seamen	40	29	—	—
Female Branch Hospital	745	753	455	—
Kandy Dispensary	120	19	6	3
Galle Dispensary	649	—	—	—

[† In addition 111,005 other cases are mentioned—probably a printer error.]

In-patient cases of *yaws* numbered 944 and at dispensaries 9 061 persons were treated. Nine deaths in the Island were due to this cause. Under the Malaria Control and Health Scheme each of the Field Medical Officers and Medical Officers of Health is responsible for the control of the disease in his area, while in other areas two whole-time Medical Officers carry on along similar lines. Each case is "carded," re-examined every six months and necessary treatment given.

Other diseases mentioned in the Report under review include the following. Hospital cases of *cancer* numbered 1,512 and hospital deaths due to this cause 168. the Registrar-General records 612 deaths under the title *Cancer and other tumours*. For *intestinal disorders* 9,830 persons were treated as in-patients and 1 194 died, for *rheumatism* 4,641 cases with 5 deaths, and for *nephritis* 3,560 cases with 637 deaths.

Scientific.—The Report of the *Bacteriological Institute* provides the usual classified statements and description of specimens received and examined and results obtained. during the year 38,294 specimens were dealt with and 115 437 doses of various vaccines prepared and issued.

At the *Pasteur Institute* 2,173 persons received preventive inoculations against *rabies*. 1 030 of these were in patients. Brains from dogs and other animals examined during the year numbered 478. of these 212 were positive with *Negri* bodies.

A considerable amount of *research work* in connexion with *nutritional* problems was carried out during the year and the results published as follows —

Report on Nutrition in Ceylon.—Sessional Paper II 1937

Further report on Nutrition in Ceylon.—Sessional Paper XXIV 1937

Vitamin A as determined by the Blue Units of the antimony trichloride test in the livers of malnourished children.—*Indian Medical Gazette* 1937 Vol 72, No 5

The Report of the *Division of Medical Entomology* describes in great detail the activities of the Division during the year. Considerable extension of work staff, equipment and laboratory accommodation is reported and described thereafter the Report proceeds to discuss at length the work carried out at the Malaria Observation Stations Mosquito and Rat flea Surveys and the Filaria Survey.

Scientific papers and books published by members of the staff of the Department of Medical and Sanitary Services included the following —

BLAZE (J. R.) Fatal Coronary Thrombosis in a man aged 25 years —*Brit Med J* 1937 Vol 2 p 14

GUNewardene (S. R.) Book in Sinhalese "Care of the Sick" for the use of the Hospital attendants

NICHOLLS (Lucius) *Framboesia tropica*—a short review of a Colonial Report concerning Statistics and *Hippelates flavipes*—*Annals of Tropical Medicine & Parasitology* 1936 Vol 30 No 3

The following publications appeared in the *Journal of the Ceylon Branch of the British Medical Association* for 1937 —

ATTYALLE (N.) The problem of carcinoma of the uterus in Ceylon

BLAZE (John R.) Heart disease in Ceylon.

FERNANDO (P. B.) Notes on a case of Encephalitis Lethargica.

GUNewardene (H. O.) Cardiovascular Autonomic Dystonia.

JAYASURIYA (J. H. F.) A case of Advanced Lymphosarcoma.

JAYAWARDENE (M. D. S.) A case of Congenital Heart Disease

PAUL (Milroy) Cure of a large Aneurysm by direct repair of the Arterial wall.

RAMANATHAN (S.) Notes on an interesting case of Acute Abdomen.

— A fatal case of Malignant Melanoma.

SENANYAKE (I. A.) Evolution of Mental Treatment.

SILVA (Stanley de) Malaria in the child.

SILVA (C. C. de) Hereditary Ectodermal Dysplasia.

VAN ROOYEN (C. A.) Reflections on the Malaria epidemic 1934-35

WIJERAMA (E. M.) The mode of onset of the malaria epidemic in Ceylon 1934-35

Medical Education—The following figures relate to the work of the Ceylon Medical College during 1937 —

Results of Examinations

Medical	Sat	Passed	Apothecaries	Sat	Passed	Mid-wives	Sat	Passed
Pre-medical	70	28	1st Apothecaries	42	22	Class I	44	30
1st Professional	60	34	2nd Apothecaries	28	14	Class II	81	65
2nd Professional	50	42	Pharmacists	22	12			
Final	50	27						

Financial—Estimated expenditure on Medical and Sanitary Services for the year 1936-37 was Rs.11,262,132, and actual expenditure amounted to Rs.11,085,271. The latter figure which represents 9.3 per cent. of the total revenue of the Island during the year does not include the cost of new buildings, or improvements to or maintenance of existing buildings.

MAURITIUS (1937).

Mauritius, an island in the Indian Ocean, is distant 500 miles from Madagascar, 834 from Seychelles, 1,300 from Natal, and 2,300 from the Cape of Good Hope. It has an extreme length of 39 miles north to south, and 29 miles extreme breadth east to west. Its area is about 720 sq. miles, equal to that of Surrey.

Vital Statistics.—The relevant facts, showing District distribution, are as follows:—

District	3rd-Year Population	Birth Rate	Death Rate	Infant Mortality Rate
Port Louis	55,791	39.3	32.6	—
Pamplemousses	35,322	29.4	31.3	—
Rivière de Rempart	32,276	34.2	27.0	—
Flacq	51,078	30.9	32.6	—
Grand Port	48,078	37.6	31.6	—
Plaines Wilhems	103,477	40.9	28.6	—
Beaune	30,683	37.4	22.5	—
Moka	29,774	30.6	23.1	—
Black River	13,270	27.3	36.7	—
The Colony	339,897	35.2	28.6	134.5

It is of interest to note that in the Black River District where the lowest birth rate and highest death rate in the Colony are recorded (and a District where the death rate greatly exceeds the birth rate) density of population is only 131.4 per square mile as against a density of 3,488.9 persons in Port Louis, and 1,328.6 persons in Plaines Wilhems. In the Colony as a whole the Indian population contributed 66 per cent. of the total births and 69 per cent. of the total deaths recorded.

Maternity and Child Welfare Work.—The two Societies, the *Maternity and Child Welfare Society* and the *Gowrie de Laet* continued to function successfully and were afforded the usual financial support by the Government (see this *Bulletin* 1937 Supp. p. 146*). The eight Government midwives attended 962 confinements and paid 4,701 house visits during the year. In the Hospital Returns it is noted that only 277 women were treated as in-patients for conditions associated with the puerperal state, and of these 160 were cases of normal labour. In the preceding year the corresponding figures were 1,878 and 1,050 respectively. The experiences in the two years differ so strikingly as to call for comment—unless the explanation lies in typographical

errors. During the year under review 169 deaths were registered as due to the puerperal state as compared with 145 deaths in the preceding year.

School Hygiene—The only information supplied which comes under this heading refers to the spleen rates of school-children the following Table summarizes the more detailed results recorded —

District	Children examined		Spleen Rates	
	1908	1937	1908	1937
Port Louis	—	1 017	—	14.1
Pamplemousses	566	1 408	65.7	31.4
Rivière du Rempart	—	1,321	—	16.1
Flacq	1 169	1 570	67.2	40.1
Grand Port	894	852	39.7	9.8
Plaines Wilhems	1 042	1 754	8.9	1.1
Savanne	420	692	29.1	9.6
Moka	393	663	13.6	0.5
Black River	275	288	41.1	33.1
The Colony	—	—	40.1	17.6

The general diminution of rates since 1908 is striking and the conclusion drawn from the above results is that the whole Island has changed from one of high endemicity to one of moderate endemicity.

Dr H ANDRÉ continued his work on Health Centre lines in the District of Pamplemousses. In four areas he examined 2,204 school children and found 408 with enlarged spleens.

Public Health Sanitation etc—No important administrative developments were recorded during the year under review the public health was good on the whole. *Anti-malarial* work continued to be carried out with unabated energy especially in the central plateau where the Malaria Branch of the Department aims at bringing this region under complete control and so provide in this area permanently healthy living conditions for the inhabitants who constitute one-quarter of the total population of the colony. For all practical purposes *sewage and refuse disposal* provision of *water supplies* etc remain unchanged (see this Bulletin 1936 Supp p 142* 1937 Supp p. 147* and 1938 Supp pp 151-152*).

With regard to *labour conditions* it is said the wages of agricultural workers were increased, plenty of employment was on offer the general health of labourers was about the average with cases of severe malnutrition extremely rare. The references to *food and drugs in relation to health and disease* remain unchanged.

The *training of sanitary personnel* was continued six candidates for sanitary posts were undergoing the course. In an Appendix to the Report under review details are supplied of the sanitary work carried out in rural areas.

Port Health Work—During the year 223 vessels arrived and 19 110 members of crews and 2,402 passengers were examined. Eighty two vessels arriving from infected ports were detained for purposes of disinfection and fumigation. In an Appendix to the Annual Report the Medical Officer of Health Port Louis provides details of anti plague precautions in and near the harbour area.

Hospitals Dispensaries etc—It is stated that Hospitals are still inadequately staffed suitable candidates for hospital posts are not available in sufficient numbers to make up normal wastages in establishment The volume of work dealt with at the various hospitals and institutions in the Colony is summarized in the Table below —

Institution	Beds	Admitted	Treated	Deaths
<i>Hospitals—</i>				
Civil	300	7,910	8,057	498
Long Mountain	65	2,028	2,047	81
Poudre d'Or	70	1,691	1,719	60
Flacq	66	2,173	2,166	117
Mahebourg	108	3,054	3,100	159
Souillac	103	334	2,417	113
Victoria	234	5,681	5,789	315
Moka	83	1,586	1,614	88
Mental	64	229	233	36
Barkly Industrial School	12	187	187	—
<i>Prisons—</i>				
Port Louis	16	300	303	4
Beau Bassin	32	303	319	5
Totals	1,180	27,517	27,968	1,476

There are 38 *Estate Hospitals* in the Colony no details of the work carried out at these institutions are supplied.

New cases dealt with at *dispensaries* and *hospital out-patient departments* numbered 211,244 and 258,575 attendances were recorded.

The notes which follow briefly summarize the references made in the Report to some of the principal items of morbidity experience during 1937.

Patients suffering from *malaria* and admitted to hospitals numbered 3,158 (3,196 treated) and 122 hospital deaths were ascribed to this cause in addition there were 47,294 *out-patient* cases. Over 11 per cent of the total hospital admissions for all causes of sickness were malaria cases while among out patients the proportion was 22 per cent. In the Colony as a whole 2,139 deaths were registered as due to malaria. The distribution of types of infection among in- and out patients reads as follows —

Infection	In-patients	Deaths	Out patients
Benign tertian	2,000	42	—
Quartan	70	—	—
Ch. tertian	78	7	—
Cachexia	628	66	3,460
Blackwater	41	9	1
Unclassified	382	3	43,822
Totals	3,196	122	47,294

Among 101 blood films examined at the Bacteriological Laboratory 14 contained *P. falciparum* 1 *P. vivax* and in 86 no parasites were found.

In an Appendix Dr L. J. MCGREGOR contributes the annual report of the Malaria Branch of the Medical Department.

No case of *plague* or *smallpox* was reported during the year. Anti-plague measures continued to be carried out. 10 228 children were vaccinated by Government Vaccinators. Of *diphtheria* 33 cases were notified. 11 cases were treated in hospital and 2 died. At the Laboratory where 331 throat and nasal swabs were cultured 38 were positive with *C. diphtheriae* and the same organism was identified in 15 out of 70 specimens microscopically examined.

An outbreak of *influenza* in June and July gave rise to some anxiety but the disease proved to be mild in type. In patient cases numbered 1 140 with 34 deaths and 28,542 persons received out-patient treatment. Deaths due to *influenza* in the Colony numbered 440.

During the year under review 80 cases of *enteric fever* were notified to the Sanitary Authority but notified cases are no reliable indication of incidence. For example Plaines Wilhems is the most salubrious district in the Colony and it has the safest water supply yet year after year notifications from this district may equal or exceed notifications from all other districts combined. (In 1937 Plaines Wilhems notifications numbered 36 and all other districts combined 44.) In rural areas where few medical practitioners are domiciled fevers of the enterica group may occur but are not notified. Hospital Returns show among in-patients 43 cases of *typhoid* with 14 deaths. 2 non-fatal cases of *paratyphoid A* and 7 cases in which the type of infection was not defined. Among 297 samples of serum submitted for agglutination tests at the Laboratory 82 agglutinated *Bact. typhosum* H and 63 *Bact. typhosum* O. [The wording of this part of the Report is peculiar. Under agglutination tests it is recorded — Agglutinated by *Bact. typhosum* H serum 82 etc. This would suggest that cultures of bacteria were sent for examination but later in the section the total number of sera submitted for examination is given and evidently the figures throughout refer to sera. No doubt the tests were correctly performed, but in the interests of scientific accuracy they should be correctly reported.]

Hospital Returns show that 712 persons were treated as in-patients for *dysentery* and 57 died while there were also 4 263 out-patient cases. Among in-patients types of infection were *amoebic* 421 cases *bacillary* 174 and unclassified 117 the corresponding figures for out-patients being 3 105 36 and 1 122 respectively. Other intestinal ailments dealt with during the year included 532 in-patient cases of *diarrhoea* and *enteritis* with 79 deaths, and under the same title 5 779 out-patient cases.

At the Laboratory where 50 faecal specimens were cultured 6 were positive with *Bact. dysenteriae* Flexner and 1 *Bact. dysenteriae* Sonne while among 1 375 faecal specimens microscopically examined *E. histolytica* was identified 77 times and *E. coli* 87 times.

Among the *deficiency diseases* recorded during the year were 102 in-patient cases of *beriberi* 3 of *pellagra* and 3 of *ricketts* and among out-patients 67 cases of *beriberi* 14 of *ricketts* and 7 of *pellagra*. In March 1937 an outbreak of *beriberi* occurred in the Central Prison Beau Bassin and 14 cases were recorded. Later the disease appeared among the prisoners of the Port Louis Prison as well. The following facts present the salient features of these occurrences —

Month	Central Prison, Beau Bassin	Port Louis Prison.
	Cases.	Cases
March	14	—
April	24	8
May	25	15
June	20	10

The outbreak subsided after June but from first to last 144 cases and 5 deaths were recorded. A Committee of Enquiry was appointed to investigate the outbreak their recommendations were adopted and improvement immediately followed.

Diseases of the respiratory system (exclusive of tuberculosis) killed 2,209 persons in 1937 this group was therefore responsible for over 19 per cent of the total deaths due to all causes in the Colony. Within this group the pneumonias were responsible for 1,470 deaths, and all forms of bronchitis for 584 deaths. Tuberculosis (all forms) caused the deaths of 329 persons during the year under review. With regard to hospital treatments for these cases the following data have been extracted from the 1937 Hospital Returns —

Disease	In-patients		Out patients
	Cases	Deaths	Cases
Tuberculosis—pulmonary	437	65	1,544
—other forms	57	8	301
Total	494	73	1,845
Bronchitis	935	48	5,003
The Pneumonias	595	178	463

Among 451 specimens of sputum examined at the Laboratory 98 were positive with *Mycob. tuberculosis*.

Although treatment for *ankylostomiasis* has been actively carried out on mass treatment lines since 1924 the infection is still apparently as widespread as ever in the rural areas. Cases treated at hospitals and dispensaries during the year numbered 18,515 and of these 2,035 were in-patients and 50 died. The usual *Annual Report of the Hookworm Branch* appears as an Appendix to the Annual Report under review. 2,364 persons were examined and 609 were found to be infected with hookworm. As regards *schistosomiasis* it is stated that adequate control measures cannot be undertaken until a systematic field investigation has been carried out. Fifty in-patient cases of *schistosomiasis* and 228 out patient cases were dealt with during the year. *Ascariasis* is a common infection. 199 in-patient and 7,235 out-patient cases are mentioned. At the Laboratory among 1,375 faecal specimens examined 863 contained *Trichuris ova*, 587 *ankylostome* and 225 *Ascaris*.

The *Annual Report of the Leper Hospital* contributed by Dr H. ANDRÉ appears as an Appendix. Four lepers were admitted during the year 1 died 4 were discharged, leaving 48 inmates resident at

the end of the year. A statement is supplied showing the type of leprosy, progress and condition etc. of each of the 48 cases. There are also 25 lepers in the Dependency of Rodrigues; details of each case are supplied with respect to sex, age, type, etc.

Veneral Diseases treated at hospitals and dispensaries were as in patients for *syphilis* 215 and for *gonococcal infections* 188 cases; among out patients were 1 086 cases of *syphilis*, 265 of *soft chancre* and 869 *gonococcal infections*. At the Laboratory, where 3 915 samples of blood serum were Kahn tested, 825 gave positive and 292 doubtful reactions. *N. gonorrhoeae* was present in 17 out of 79 specimens of pus etc. examined.

Scientific—Owing to prolonged illness of the Pathologist Dr H D TOUJAG, the Report of the Bacteriological Laboratory takes a more abbreviated form than usual. Altogether 8 276 specimens were received, examined and reported upon; the more important of these have been the subject of brief mention in various sections of the preceding notes.

Scientific papers published by members of the Staff of the Medical and Health Department included the following—

WERN (J. L.) On the occurrence of dysentery like organisms in the Urinary Tract of man in Mauritius.—*Jour Hygiene* Vol. 37 No. 2, 1937.

— The helminths of the intestinal canal of man in Mauritius and a first record of *Trichostrongylus axei* locally.—*Jour Parasitol* Vol. 29 No. 4 p. 469.

— Notes on Filariasis and its transmission by Mauritian Anophelines.—*Trans Roy Soc Trop Med & Hyg* Vol. 30 p. 477.

The following is a list of the Special Reports which appear as Appendices to the Annual Report under review—Annual Reports of The Bacteriological Laboratory, The Government Analyst, The Hookworm Branch, The Malaria Branch, The Medical Officer of Health, Port Louis, The Mental Hospital, The Leper Hospital, The Radiologist, The Medical Officer, Rodrigues.

Financial—Total expenditure on Medical and Sanitary Services during 1937 amounted to Rs. 1 585,275, a sum which represents approximately 10 per cent of the revenue of the Colony during the same period.

SEYCHELLES (1937)

The Seychelles Islands, 92 in number, are situated in the Indian Ocean between 4° and 10° S latitude. Their total area is estimated as 156 sq miles. Mahé, the largest, is 17 miles long and 3 to 7 broad, with an area of 56 sq miles.

Vital Statistics—The estimated population at the end of the year was 30 940. Registered births numbered 827 and deaths 440; the resulting crude birth and death rates being 28.7 and 14.2 per 1 000.

respectively. Infant deaths numbered 67 and the infant mortality rate 81 per 1 000 live births. [By comparison with 1936 experience the crude death rate and the infant mortality rate show increases.]

Neither the numbers of the *general European population* nor of *European Officials* are supplied. During the year 3 Europeans died and 845 officials from various Government Departments were treated at Headquarters in Victoria. officials treated by Assistant Medical Officers in the Districts are not included. [During the preceding year 632 officials were treated at Headquarters.]

Maternity and Child Welfare Work—To the Maternity Section of the Seychelles Hospital 295 patients were admitted. in the 240 normal labour cases birth was given to 224 live babies. there were 11 stillbirths, and 3 maternal deaths. At the Cottage Hospital Praslin the 44 patients in the Maternity Section included 37 labour cases. 34 live births were recorded.

Ante-natal and Infant Welfare Clinics continued to be held as previously described (see this *Bulletin* 1936, Supp. p. 157*) and 114 women and 536 children attended these centres during the year. The training of probationer nurses continued to be carried out at the Seychelles Hospital, the course of training covering three years.

School Hygiene—There are now 29 grant-in-aid elementary schools controlled by Government and 2 secondary schools not under Government control. Government-controlled schools were inspected periodically by Medical Officers during the year. The principal findings recorded were as follows—

	Schools of		
	Mahé	Praslin	La Digue
Number examined	942	290	161
Defects noted (percentages) —			
Lack of cleanliness	10.6	20.7	14.6
Nutritional deficiencies	11.1	11.4	12.0
Dental caries, etc.	26.2	6.9	2.1
Intestinal parasites	69.9	9.4	9.5
Enlarged tonsils, etc.	11.4	1.9	1.2
Skin diseases	7.0	4.6	3.9

It is stated also that among the children attending Mahé schools 75 per cent. showed diseases of the nervous system and 37 per cent. diseases of the circulatory system.

Children in Government-controlled schools receive regular instruction in elementary hygiene.

Public Health Sanitation etc.—Dr E. M. LAMIER, Senior Medical Officer, reports that the health of the population was "fairly good," with the prevalence of influenzal and respiratory affections at times high. [It has been observed (see *Vital Statistics* above) that general mortality and infant mortality rates were higher than in 1936. more in- and out-patient hospital treatments were also recorded than in the preceding year.] The health value which would follow the establishment of hull stations for the use of residents during the hot weather months is again emphasized (see this *Bulletin* 1936, Supp. p. 158*).

The responsibilities of the Victoria Town Board and the Local Boards of Health in regard to general measures of sanitation remain as previously described. Methods of *sewage and refuse disposal* are unchanged. It is said that the number of septic tank installations in private houses is increasing. At ordinary times the *water supplies* of the Colony are adequate and free from pathogenic organisms. After heavy rains it has been noted that the incidence of bowel diseases appears higher and at such times the filtering and boiling of the water becomes necessary. Reference is again made to the need for the appointment of a ranger to patrol the water reserves (see this *Bulletin* 1938 Supp. p. 157*). The comments upon the Seychellois labourers remain as previously described. Towards the end of the year a mild outbreak of polyneuritis of obscure origin was reported among the labourers on the island of Coetivy. The outbreak was investigated and was thought to have been of toxic origin. The outbreak subsided and no fatality was reported.

The usual routine inspections of *foods* etc. exposed for sale were continued. During the year the restrictions placed on the manufacture of toddy were removed. In a country where polished rice is widely used the drinking of toddy in moderation provides a valuable addition to the usual diet for toddy yeast is rich in Vitamin B complex. The removal of restrictions on the manufacture may result in the improvement of the state of nutrition of the people of the Colony if proper use is made of this valuable food.

The training of sanitary personnel was continued. Lectures and demonstrations are given throughout the year on all subjects necessary for the efficient performance of duties by sanitary inspectors.

Recommendations for future work repeat the recommendations made in the 1936 Report (see this *Bulletin* 1938 Supp. pp. 158*-159*).

Port Health Work—The constitution and organization of the Port Sanitary Authority remain unchanged. During the year 58 vessels called at Mahé and 450 passengers entered the Colony. One ship was placed in full quarantine and 18 saloon passengers were accommodated on Quarantine Island. The accommodation in the Island is inadequate in view of the development of the tourist industry and the increasing number of passengers landing in Mahé.

Hospitals Dispensaries etc.—The volume of work dealt with during the year at various Government institutions may be summarized as follows:—

Institution	In patients			Out-patients
	Admitted	Treated	Died	Treated
Seychelles Hospital, Victoria	1,395	1,413	19	6,464
Cottage Hospital, Praslin	89	7	3	—
Lunatic Asylum	6	37	—	—
Pauper Asylum	63	68	42	—
Dispensary South Mahé	—	—	—	2,753
" Bay St. Anne	—	—	—	1,606
" Grand Anse	—	—	—	345
" La Digue	—	—	—	512

Malaria does not exist in the Colony, but three imported cases were treated in the Seychelles Hospital. The measures taken to prevent possible introduction of anophelines continued to be applied (see this *Bulletin* 1938 Supp. p. 159*). Sporadic cases of *dengue fever* occur from time to time—only 1 hospital case is recorded. It is again stated that *elephantiasis* of the legs and scrotum is not uncommon and that cases of *lymphangitis* and *hydrocele* probably of filarial origin, are frequently seen.

Influenza is said to be very prevalent at certain times of the year. 62 cases were treated in hospital and 6 deaths in the Colony were ascribed to this cause.

Dysentery was responsible for 20 hospital cases, all of the *amoebic* type and 2 deaths were registered under this title in the Colony. In the returns of the Praslin Cottage Hospital 4 cases of *amoebic hepatitis* and 1 of *amoebic dysentery* are mentioned. At the Seychelles Hospital 45 patients were treated for *diarrhoea and enteritis* and 2 died.

Five cases of *pulmonary tuberculosis* and 3 of other forms of the disease were treated in the Seychelles Hospital, and 18 deaths were registered in the Colony as due to tuberculosis of the respiratory system. Other respiratory affections mentioned in the Seychelles Hospital Returns included 14 cases of *bronchitis* and 18 of *pneumonia*. Deaths in the Colony due to pneumonia numbered 22, and to bronchitis 5.

Antylostromiasis continues to be responsible for the majority of the cases of secondary anaemia and chronic ill-health seen among the poorer classes and natives (see this *Bulletin* 1938, Supp. p. 160*). Mass treatment at regular weekly intervals was carried out at 17 centres. [It is stated that the number of patients treated totalled 17 063 (in a total population of 30,940) while in another place a total of 17 063 treatments is mentioned.]

The incidence of *leprosy* remains high. During the year 6 new cases were discovered, 1 during the course of inspection of a Boys' School in La Digue where a child was found suffering from the maculo-anaesthetic type of the disease and another a girl aged 12. At the end of the year there were 88 known lepers in the Colony. Attention is called to the fact that more infective cases are segregated at home than on leper islands—this system of home isolation is unsuitable, for the leper patients rarely observe the regulations. The work at the new settlement on Curieuse Island (see this *Bulletin* 1938 Supp. p. 160*) progresses satisfactorily and it is expected that the male section will be ready for occupation in 1938. In course of time all the infective cases will be segregated on this Island. The leprosy clinics at Victoria, South Mahé, Praslin, and La Digue continued to function throughout the year.

Veneral diseases are said to be "extremely prevalent" and responsible for much invalidism—diseases of the circulatory system, many of them of syphilitic origin, and rheumatic affections of gonococcal origin are very common. The true incidence of these diseases cannot be stated owing to the lack of a properly organized system of control. V.D. clinics function at four centres. The 36 in-patient cases treated at the Seychelles Hospital included 19 cases of *syphilis* and 20 of *gonorrhoea* and its complications. Seventeen deaths were registered in the Colony as due to venereal diseases.

With regard to *other diseases* mentioned in the Report it is noted that no case of *smallpox* was reported the regulations governing the compulsory vaccination of children passengers arriving and labourers proceeding to outlying islands continued to be enforced (see this *Bulletin* 1938 Supp p 159*) During the year 781 children were vaccinated. The incidence of *cancer* and other tumours appears high 19 deaths were ascribed to this title in 1937 The returns of the Seychelles Hospital show that 34 patients were treated for *hernias* 34 for *appendicitis* and 65 for *affections of the liver* (including 58 cases of *hepatitis*)

The *Special Annual Medical Reports* of the Assistant Medical Officer South Mahé and of the Assistant Medical Officer Praslin and La Digue are presented as Appendices to the Annual Report under review

Scientific—Routine examinations of specimens of various kinds are carried out in the small laboratory of the Seychelles Hospital The year's work included the application of the Kahn test to 85 samples of serum with positive reactions in 39 cases the examination of 14 samples of sputum, 6 of which were positive with *Afyco tuberculosis* and the examination of 19 smears etc 5 of which contained *Afyco leprae*. A new laboratory building is in course of erection

Financial—Actual expenditure on Medical and Sanitary Services during 1937 amounted to Rs. 90,219

FAR EAST

BRITISH MALAYA.

Introductory—During 1937 a further step towards the compilation of a Pan-Malayan Medical Report was taken (see this *Bulletin* 1938, Supp. p 162*) by the inclusion of certain details relating to the Unfederated Malay States. For purposes of the present *Supplement* and in order to maintain comparisons with previous issues, each of the areas concerned is separately described in the pages which follow. The Report continues the practice of presenting an admirable series of photographs illustrative of various phases of Public Health work in British Malaya.

STRAITS SETTLEMENTS (1937)

The Colony of the Straits Settlements, the collective name given to the Crown Colonies formed by the British possessions on or adjacent to the mainland of the Malay Peninsula, as opposed to the Federated and Unfederated Malay States, consist of the island of Singapore with about a score of small islets lying in its immediate vicinity, the town and territory of Malacca, the island of Penang and Province Wellesley and the island of Labuan. The total area is about 1,357 sq miles (Singapore, 220 sq miles. Penang and Province Wellesley 400 sq miles. Malacca, 640 sq miles) and Labuan, 35 sq miles.

Vital Statistics—The estimated population and its racial and local distribution in the middle of the year under review was as follows—

Race	Singapore	Penang	Province Wellesley	Malacca	Labuan	Total
Europeans	11,640	1,944	309	473	31	14,397
Eurasians	7,591	2,209	289	2,299	44	12,402
Malayans	70,783	40,193	73,614	104,839	3,131	294,565
Chinese	495,854	141,917	52,700	77,479	2,693	770,645
Indians	48,969	31,007	77,355	28,565	149	142,073
Others	8,642	1,781	84	829	63	11,657
Totals	651,486	219,031	154,809	212,232	8,111	1,245,739

Registered births numbered 52,433 and the crude birth rate (all races) was 42.1 per 1,000. *Registered deaths* numbered 27,974 and the crude death rate 22.5 per 1,000. The *Infant Mortality Rate* was 155.8 per 1,000 live births, a decrease of 15.1 by comparison with 1936 experience. The fluctuations in the infant mortality rate are commented upon, and it is pointed out that the highest rates still occur in districts which have a pre-eminently Malay population.

The *Registration of Births and Deaths Ordinance* (1937) which was passed during the year provides for the compulsory registration of stillbirths and for the introduction of changes in method from time to time for the purpose of ensuring the assembly of more accurate data.

Maternity and Child Welfare Work—There are Government maternity hospitals in Singapore and Penang maternity blocks attached to the General Hospitals at Singapore and Malacca and maternity wards or beds are also available at most of the Government District Hospitals in the St. Andrew's Mission Hospital Singapore and in the Kwong Wai Shiu Hospital Singapore—the latter a charitable institution supported by the Chinese community. Plans for an extension of Kangang Kerbau Hospital have been approved and constructional work proceeds.

The Table below summarizes the principal details of maternity work dealt with at various institutions during 1937—

Centre and Institution	Admissions	Deliveries	Maternal Deaths
<i>Singapore—</i>			
General Hospital	583	549	7
Maternity Hospital Kangang Kerbau	5 625	5,214	83
St. Andrew's Mission Hospital	?	489	?
Kwong Wai Shiu Hospital	?	615	?
<i>Penang—</i>			
King Edward VII Maternity Hospital	2,353	2,073	15
District Hospital Province Wellesley	?	275	?
<i>Malacca—</i>			
General Hospital	?	812	?
District Hospitals	?	—	?

Asiatic midwives are attached to many of the smaller district hospitals and every effort is made to persuade Malay women to take advantage of the medical facilities provided. The training of midwives at various centres was continued (see this *Bulletin* 1936 Supp p 161*). Registered midwives in the Colony in 1937 numbered Class A 315 Class B 846 and Class C 321.

Infant and Child Welfare services are provided by the Government in rural districts and by the Municipalities in urban areas. At the 24 Government centres and 9 sub-centres 224,835 visits to homes and 197 418 attendances at clinics were recorded. There are 3 Municipal clinics in Singapore 2 in Penang and 1 in Malacca and these services recorded 202,742 visits to homes and 67 519 attendances at clinics.

In addition to the above there are *Women's and Children's Dispensaries* in the large towns and at these centres the 49 423 new patients treated included 23 617 children.

School Hygiene—The arrangements made for the inspection of schools and school-children have been described in previous issues of this *Supplement*. The following notes briefly summarize the principal items of work carried out in 1937.

Singapore—Visits were paid to English Malay and Chinese schools and 11 477 boys and 8 937 girls were medically examined, 19 per cent of the boys and 67 per cent of the girls examined being referred for treatment. In Boys' Schools 36 per cent and in Girls' Schools 47 per cent of the pupils examined showed dental defects. Enlarged tonsils and adenoids were found in 12.6 per cent of the girls but only 0.9 per

cent. of the boys. Among boys attending Malay Vernacular Schools 52 per cent. of those examined showed infestation with hookworm, but only 8 per cent. of the Malay girls examined were similarly infested. Evidence of gross malnutrition was rare, but less marked deficiency difficult to assess as it does not amount to actual ill-health, was observed in about 10 per cent. of the children examined.

Penang—Pupils examined in *English Boys Schools* numbered 4,757 and of these 59 per cent. showed dental caries, 3.6 per cent. defects of nose throat and ear and 4.1 per cent. skin affections. In *English Girls Schools* 2,328 pupils were examined and results showed 40.4 per cent. with dental caries, 8.8 per cent. with defects of nose, throat, and ear and 5.1 per cent. with skin affections. In *Malay Vernacular Schools* among 3,250 boys and 2,480 girls examined 72 per cent. of the boys and 46.6 per cent. of the girls had dental defects, 7.8 per cent. of the boys and 9.7 per cent. of the girls defects of nose throat, and ear and 6.4 per cent. of the boys and 6.2 per cent. of the girls skin affections. Boys in Malay Vernacular Schools are usually examined for worm infestations. During the year 847 school boys in urban and 1,895 in rural schools were examined. 27.5 per cent. of the former were found to be infested with hookworm and 80 per cent. with roundworm, the corresponding figures for infestations in rural schools being 59 and 76 per cent. respectively. In Malay Girls Schools 91.6 per cent. of the pupils examined were found to have verminous heads.

Province Wellesley—Pupils examined in English and Vernacular Schools numbered 4,157. Of these 34.5 per cent. showed dental defects, 11.6 per cent. skin affections and 8.8 per cent. ear nose and throat defects.

Malacca.—The results of the annual examinations read as follows —

Item	English Schools		Malay Vernacular Schools	
	Boys	Girls	Boys	Girls
Pupils examined	1,639	777	8,709	340
With carious teeth	297	383	3,454	212
Enlarged spleens	16	0	439	0
totals	157	163	1,898	84

Sixty four Chinese schools were also visited and the pupils medically examined but no details are supplied.

Public Health Sanitation, etc—Anti-malarial work undertaken in the various Settlements is described in some detail. Methods of *sewers and refuse disposal* have been described in previous issues of this Supplement (see this *Bulletin* 1937 Supp., p. 167*). In Singapore and Penang sewers are steadily being extended. The need for an efficient and safe manure in rural areas and for more rigorous control of nightsoil and refuse disposal has led to experimental work in methods of disposal by *composting*. The experiment is still in progress.

Water supplies remain for all practical purposes as previously described (see this *Bulletin* 1937 Supp., p. 167* and 1938 Supp. p. 172*). In Province Wellesley constructional work was resumed at

Chero To Kun Dam and a start was also made with the filter station at Bukit Mertajam. In the Northern District a preliminary survey was made by the Public Works Department in connexion with a filtered supply from the Mda River.

Progress is reported in the direction of ensuring that *foods and drinks* shall be prepared and sold under conditions which will reduce the risk of gross contamination and special efforts are directed towards the control of food hawkers. *Housing* in the Municipal area of Singapore is referred to in the summary of the Report of the Municipal Medical Officer of Health.

Regular visits of inspection continue to be made to *estates* by Officers of the Health Branch of the Medical Department. It is said that owners and managers of estates appreciate the advice and recommendations made by visiting officers.

The *training of sanitary personnel* was continued. Ten private and 10 Government students attended the course for the certificate of the Royal Sanitary Institute London. 24 candidates sat for the examination and 15 were successful.

Port Health Work—Quarantine measures were imposed against a number of ports and airports in the Far East for smallpox, cholera and plague. Though no case of *cholera* occurred among the general population there were 38 cases and 16 deaths all imported from infected ports and dealt with at the St. John's Island Quarantine Station. The jurisdiction of the Government Health Department in the *Civil Airport* area was extended to include the sanitary control of aircraft examination of crews and passengers etc. From April to the end of the year 159 aeroplanes with crews numbering 529 and 583 passengers were dealt with. A series of experiments to determine how mosquitoes stand journeys by air were carried out by the Health Officer Karachi in co-operation with the Medical Officer Singapore. *Anopheles Culex* and *Aedes* were used in these experiments. The death rate among the mosquitoes was 4 per cent. and the surviving mosquitoes showed unimpaired activity. Other details of Port Health work can be summarized as follows:—

	Singapore	Penang	Quarantine Stations
Ships examined	823	401	—
Infected ships	0	1	—
Crews examined	103,250	39,212	—
Passengers examined (including immigrants, pilgrims, etc.)	320,584	158,383	—
Rats trapped and examined	1,255	?	—
Rats plague infected	0	?	—
Passengers admitted	—	—	71,505
Total sick treated	—	—	1,219
Total deaths	—	—	58
Cases of cholera	—	—	13
Cases of smallpox	—	—	2

Hospitals Dispensaries etc—The following Table briefly summarizes the volume of work dealt with at various institutions (exclusive of Leper Settlements) maintained by the Medical Department:—

Item	In-patients		Out patients
	Treated	Died	
Singapore—			
8 Hospitals	38,011	3,940	33,779
Dispensaries	—	—	39,420
Travelling Dispensaries	—	—	20,491
Penang & Province Wellesley—			
8 Hospitals	22,920	1,543	51,766
Dispensaries	—	—	28,238
Travelling Dispensaries	—	—	42,900
Malacca—			
2 Hospitals	10,120	772	15,432
Dispensaries	—	—	25,170
Travelling Dispensaries	—	—	19,515
Labuan—			
1 Hospital	268	13	1,333
Travelling Dispensaries	—	—	1,490

According to the above figures 71,319 in patients were treated in all hospitals and 6,268 died in another place it is stated that hospital admissions numbered 73,884 and hospital deaths 6,708. The out-patient figures do not include patients treated in special clinics, Infant Welfare Centres, school-children, etc.

Sections of the Report under review briefly comment upon the work of such specialist services as *Ophthalmology Radiology Dental Surgery* etc.

The incidence of malaria can only be guessed at by reference to the recorded hospital cases, and these facts as given are unsatisfactory. In one place the number of patients admitted to Government hospitals and diagnosed malaria is given as 8,625 in another place it is said the total classified cases (malaria) was 6,375 and yet in the classified Hospital Returns admissions for malaria total 8,638 distributed as to *benign tertian* 1,839 *quartan* 193 *subtertian* 4,120 *blackwater fever* 3 mixed and other infections 557 and unclassified 1,828. One table shows 298 hospital deaths due to malaria (includes 1 due to *blackwater fever*) and another 292 deaths.

Deaths due to malaria in the Straits Settlements as a whole numbered 1,185.

The Fourth International Course in Malarology was held at the King Edward VII College of Medicine Singapore, and attended by 17 graduates from seven countries. The general arrangements were similar to those in previous years but there was in 1937 closer collaboration between field and laboratory work, and more time devoted to field surveys. Following completion of the Singapore part of the Course practical field studies were continued in Malaya, Java, and Indo-China.

No case of *cholera* or *plague* occurred among the general population. 38 imported cases of *cholera* were dealt with at the Quarantine Stations. An outbreak of *smallpox* in Kedah was reported one concealed case was discovered and 3 contacts developed the disease. There were no deaths. Government Health Department Officers performed 127,457

vaccinations 96,331 were done in the Penang area following the outbreak in Kedah. Thirty five cases of *tropical typhus* (includes 2 cases of Japanese River Fever) were dealt with in hospitals two of the cases terminated fatally. According to Hospital Returns 20 patients were admitted suffering from *cerebrospinal meningitis* and 7 of them died. 14 deaths were ascribed to this disease in the Straits Settlements as a whole.

Food sold by the numerous itinerant hawkers continues to be a common cause of infections of the *enterica* group of fevers (see this *Bulletin* 1938 Supp. p. 174*). During the year 371 in-patient cases of *typhoid* with 81 deaths and 14 of *paratyphoid fever* with 1 death were dealt with. In the Straits Settlements as a whole 110 deaths were registered as due to enteric fever. At the Laboratory 1,393 samples of blood serum were received for agglutination tests and the following positive results recorded: *Bact. typhosum* 393 *Bact. paratyphosum* A 16 B 12, and C 7. *Bact. typhosum* was isolated from specimens of urine on 39 occasions and positive clot cultures of this organism were obtained from 152 specimens of the samples of blood serum examined.

Of the 688 cases of *dysentery* treated in hospitals with 161 deaths 313 were amoebic (46 deaths) 287 bacillary (96 deaths) 8 were mixed infections (7 deaths) and 80 were undefined (12 deaths). Deaths in the Colony as a whole due to *dysentery* numbered 275 and in addition 1,373 deaths were ascribed to *diarrhoea and enteritis*. Hospital cases of *diarrhoea and enteritis* totalled 1,727 with 476 deaths and of these 734 of the cases and 390 of the deaths relate to children under two years of age. From the examination of 2,724 faecal specimens at the Laboratory the following organisms were isolated: *Bact. dysenteriae* Flexner 213 Schmitz 11 Shiga 10 Sonne 4.

Tuberculosis continues to be one of the most important causes of death and disablement in the Straits Settlements. *Pulmonary tuberculosis* was the registered cause of 2,268 deaths and other forms of tuberculosis caused 196 deaths. Of the total deaths due to tuberculosis (all forms) in the Colony 1,475 occurred in the Municipal area of Singapore. The treatment of the disease in Government hospitals continues as in former years. It is said that more patients are presenting themselves for treatment at a comparatively early stage of the disease (see this *Bulletin* 1938 Supp. p. 174*). Hospital cases of tuberculosis (all forms) numbered 2,691 with 992 deaths and of these 2,649 of the cases and 879 of the deaths were due to the *pulmonary* form of the disease. There were 2,048 cases of *pneumonia* (all forms) treated in hospitals with 1,182 deaths and 1,438 cases of *bronchitis* with 29 deaths.

As has been observed in previous years the incidence of *beriberi* is closely related to the general prosperity of the Colony—with incidence higher as a rule during good years (see this *Bulletin* 1938 Supp. p. 175*). During the year under review 1,385 in-patient cases were dealt with in the various Colony hospitals and 237 of these patients died.

Leprosy.—Although during the year under review there was a decrease in the number of patients seeking admission to the Leper Settlements in the Colony the problem of accommodation continues to give rise to concern. From the special section of the Report dealing with the activities at the various Settlements the following details have been extracted:—

Item	Lepet Settlements	
	Singapore	Pulau Jerejak, Penang
Patients admitted 1937	193	234
treated	417	1 431
discharged	7	1*
reconded	36	?
died	8	151
transferred	134	—
remaining at end of year	23*	1,205

Of the 1,205 patients at the Pulau Jerejak Settlement 896 were Chinese and 188 Indians (see this *Bulletin* 1938 Supp. p. 174*)

Veneral Diseases.—The majority of cases of venereal disease are treated in the special out patient clinics which are under the control of the Chief Medical Officer Social Hygiene (see this *Bulletin* 1938, Supp. p. 175*) but a considerable number of patients are admitted to and treated in hospitals the following figures relate to in-patients only —

	Syphilis	Gonorrhoea	Soft Chancres	Tropical Bubo	Other V.D.
Cases.	1 305	821	419	180	250

Out-patients (new cases) applying for treatment at the special clinics numbered 22,814 and of these 6 155 were suffering from syphilis, 4 432 chancroid and 6 027 gonorrhoea. During recent years there has been an increase in the number of patients treated for soft chancre and gonorrhoea, and a decrease in the cases of syphilis. A very considerable disproportion is observed between the numbers of males and females treated, e.g. syphilis males 5,382, females 773 soft chancres males 4 424 females 8 gonorrhoea males 5 729 females 298.

At the Special Clinic provided for the treatment of seamen 1 099 seamen were treated of these 493 were Chinese 357 British, and 161 non British Europeans.

It is said that recorded cases at the various treatment centres are not necessarily a true indication of the incidence of venereal diseases in the Colony members of the naval and military forces when infected are treated by their own medical services, and among the general population a considerable number of patients will be treated by private practitioners, and by "Eastern methods," etc.

Among other diseases the following appear worthy of mention. An appreciable increase in the hospital admissions for cancer is noted—684 cases with 247 deaths. *Helminthic diseases* are not mentioned in the text of the Report, but Hospital Returns supply the following facts relating to in-patient cases *ankylostomiasis* 1 632 cases with 13 deaths *ascariasis* 613 cases with 19 deaths *dracontiasis* 13 cases with 1 death other helminths 38 cases.

Other references in the Hospital Returns include 1 910 cases of *influenza* with 20 deaths 840 cases of *nephritis* with 206 deaths, and *hernias* were responsible for 357 cases and 31 deaths. The increase in mechanized traffic is reflected in the 882 admissions to hospitals due to motor accidents and 75 deaths.

Scientific—The year's work at the *King Edward VII College of Medicine* Singapore is described as usual and in some detail. Twenty-four medical and 12 dental students were admitted during 1937 18 medical and 4 dental students passed their final examinations and at the end of the year there were 106 medical and 61 dental students on the books of the College.

Research activities have always figured prominently in the work of the different Departments of the College and included the following studies during 1937. In the Department of Biochemistry research work in local foodstuffs was continued (see this *Bulletin* 1937 Supp p 170* and 1938 Supp p 176*) while the Department of Bacteriology devoted attention to various aspects of the *juncus* problem. The patients admitted to the Tan Tock Seng Hospital are providing opportunities for the study of differences in diet and of deficiency disorders among the various peoples of Malaya. It had been noted that many patients are admitted suffering from a deficiency disease alone many others from diseases in which a deficient diet is an important contributory factor that macrocytic nutritional anaemias are almost exclusively seen amongst Indians and that what is believed to be a deficiency disease affecting the sensory side of the nervous system (in contrast to dry beriberi which mainly affects the motor system) is met with among Chinese patients. These matters are under investigation. Scientific papers published by members of the staff included the following—

FELL (W. A.) Development of the skull of *Ornithorhynchus*—*Trans Zool Soc* Part I 1936

and the following articles published in various issues of the *Journal of the Malayan Branch of the British Medical Association*—

CALDWELL (A. F.) The Chemistry and Preparation of Pyrethrum Spray
OLIVEIRO (C. J.) Basal Metabolism in Singapore.

— A Survey of Singapore Children in regard to their weight, height, and nutrition

SMITH (C. E.) The Histidine Treatment of Gastric Ulcer

— The Synthesis of Hippuric Acid as a Liver Efficiency Test.

HARIDAS (G.) Infantile Beriberi.

— Liver Efficiency Tests.

— Tuberculosis in Infants and Children.

MONTEIRO (E. S.) A Case of Gout.

— A Case of Lathyrism.

— Some Observations on the Action of Kadal Ranji in Diabetes Mellitus.

PALLISTER (R. A.) Some Observations on Pulmonary Tuberculosis in Singapore.

HAWES (R. B.) MONTEIRO (E. S.) & SMITH (C. E.) The Treatment of Acute Beriberi or 'Shoshin' with massive doses of Vitamin B

The Report of the Pathological Branch describes the year's work at the laboratories established in Singapore Penang and Malacca the principal items of routine work may be summarized as follows—

	Singapore	Penang	Malacca
Serological tests for syphilis	15 181	8 461	4,332
Cultural examinations	4,333	3 427	1,203
Angiostriation tests	2 064	373	684
Histological sections examined	3 163	180	83
Autopsies	1,587	180	119

Financial—Expenditure on Medical and Health Services in each of the Settlements and in the whole Colony was as follows —

Singapore	\$2 139,240
Penang	1,066 063
Malacca	393 007
Labuan	22 747
Total	\$3,628 059

Penang, Straits Settlements.

MUNICIPAL HEALTH OFFICER'S REPORT ON THE HEALTH OF THE MUNICIPALITY OF GEORGETOWN PENANG 1937

Statistical Statistics—The relevant facts may be tabulated as follows —

Race	Estimated Population	Births	Birth Rate	Deaths	Death Rate	Infant Deaths	I.M.R.
European	1 325	56	42.3	6	4.5	—	—
European	1,330	50	22.4	26	11.6	—	—
Chinese	114,292	4,547	39.8	324	29.2	607	133
Malay	1,602	490	32.7	386	17.9	71	145
Indian	27,230	732	28.0	445	16.3	86	113
Others	1 968	34	17.1	21	10.8	4	118
Totals	168,667	5,839	35.0	3,205	19.0	768	129

The above facts are presented in considerable detail in the Report under review. The gross total of deaths within Municipal limits during the year was 3 697 but of these 489 were *non-residents*. Intestinal diseases, respiratory diseases, prematurity and convulsions were responsible for 580 of the 786 infant deaths recorded, while of the total deaths in this group 30.9 per cent occurred within the first month of life and 40 per cent between three months and one year.

Maternity and Child Welfare Work continued at the two Clinics, Kimberley Street and Coombe Lines Road (see this *Bulletin* 1938, Supp. p. 177*) and details of the volume of work include the following—First attendances, Kimberley Street 1 775 re-attendances 6 590 Coombe Lines first attendances 671 re-attendances 2,057 these details are classified by race and disease incidence among patients.

At the Kimberley Street Clinic 149 women attended for ante-natal advice and supervision and the corresponding number at the Coolie Lines Road centre was 76. Infant work continued with success at both centres. As in former years District Visiting was carried out by two Health Sisters assisted by locally qualified midwives and during the course of this work 59 651 visits were paid. Midwives registered under the Midwives Ordinance were Class A 90 Class B 295 and Class C 10. The chief causes of infant mortality were referred to in the section *Infant Statistics* above. It remains to say that following an investigation of infant mortality it was noted that such deaths were more numerous in congested areas of the Municipality and that in some cases it would appear that the teaching of Health Visitors is disregarded when such visits cease when infants are three months old. Extension of the district work is recommended.

Public Health Sanitation etc.—There is nothing new to add to former accounts of the services concerned with the collection and disposal of *night soil and refuse* (see this *Bulletin* 1936 Supp. p. 169* 1937 Supp. pp. 172*-173* and 1938 Supp. p. 178*). *Water supplies* throughout the year are said to have been ample and of good quality.

The Chief Sanitary Inspector contributes his Annual Report of the work of his Department (see this *Bulletin* 1938 Supp. p. 178*).

No description of *Hospitals or Dispensaries* within the boundaries of the Municipality is supplied but the facts concerned with *morbidity experience* are tabulated in some detail the principal of these are summarized hereafter.

Twenty six deaths were ascribed to *malaria*. All were investigated with a view to the discovery of the probable origin of infection. Of 2 cases within the Municipality 1 was diagnosed clinically or on hearsay evidence of relatives just prior to death and of 6 described as unknown who died in hospital no information was available. It is said the numbers of malaria-carrying mosquitoes continues to decrease. But though only 6 deaths were ascribed to malaria no less than 458 appear in the Returns as due to *Unspecified Fever* 288 of these occurring among the Chinese members of the community.

The notified cases of the *principal infectious diseases* include tuberculosis 312 chickenpox 176 enteric fever 88 measles 34 diphtheria 29 puerperal fever 16 influenza 13 erysipelas 6 and cerebrospinal meningitis 2.

Of the 88 cases of *enteric fever* notified 60 were treated in hospital with 14 deaths, and among the remaining 28 cases 10 died. The distribution of the disease is general throughout the Municipality and the number of cases has shown a tendency to increase year by year. In the course of his discussion of probable sources of infection Dr W. H. BRODIE observes that one source which has not been effectively dealt with is the street hawker of foods and drinks. The rigorous licensing of this class of street trader would help to solve the problem. Thirty deaths were ascribed to *dysentery* 102 to *diarrhoea* and 81 to *enteritis* but no comment on any of these causes is supplied. It is noted that 96 per cent. of the deaths due to enteric fever 89 per cent. of those due to enteritis 80 per cent. of the dysentery deaths and 78 per cent. of the deaths ascribed to diarrhoea occurred among the Chinese.

Tuberculosis as a cause of death is only exceeded by the title "Unspecified fever" for during the year under review all forms of tuberculosis caused the deaths of 312 persons and of this total 293 were due to the *pulmonary* form of the disease. *Pneumonia* was the cause of death in 166 cases, *bronchitis* in 137 while *other respiratory diseases* were responsible for 274 deaths.

Fifty-six deaths were due to *beriberi* and of these 51 occurred among the Chinese while of the 26 cases of *puerperal fever* notified, 13 terminated fatally.

No mention of *venereal diseases* is made, though it is noted that 21 deaths were due to *syphilis*. No case of *plague* or *smallpox* occurred. The rat-catching gang continued their activities and were successful in destroying 7,342 rats. Within the Municipal limits practically all vaccinations are carried out by the house-to-house visits of whole-time vaccinators who during the year performed 4 153 primary and 223 secondary vaccinations private practitioners performed 563 primary vaccinations.

Financial—The total expenditure on Municipal Medical Services during 1937 amounted to \$171 091 or deducting revenue \$158,552.

Municipality of Singapore (1937)

Vital Statistics—In the previous issue of this *Supplement* an account was given of the peculiar difficulties encountered when attempting to estimate the intercensal population of Singapore, the methods of calculation employed in the past, and the reasons leading up to the adoption of the *Wieland* method in 1936 (see this *Bulletin* 1938 Supp. p. 180*). In the Report under review Dr P. S. HUTTON, Municipal Health Officer again refers to this estimation problem, adheres to the *Wieland* method in preparing the estimate for 1937 and explains that the method has been applied to Chinese, Malays, and Indians only since the numbers for other nationalities are so small that indices would be unreliable. The problem of estimation was further complicated in 1937 for with the outbreak of hostilities in China there followed a big influx of Chinese official figures show an excess of Chinese arrivals over departures in Malaya of 158,803 and no doubt many remained in Singapore—according to some estimates 70 000 Chinese refugees took up their abode in the Municipality. The relevant vital statistical facts for 1937 read as follows—

Race	Estimated Population	Births	Birth Rate	Deaths	Death Rate	Infant Deaths	I M R.
Europeans	8 478	248	28.9	47	5.5	3	12.2
Europeans	7 248	191	26.4	90	12.4	21	109.9
Chinese	398 873	18,577	46.6	9 455	23.7	3,203	172.4
Malay	50 365	1 982	38.9	1 154	22.9	451	229.9
Indians	46,533	1 355	28.9	83*	17.8	189	130.3
Others	8 367	291	34.8	106	12.9	21	72.7
Totals	520 164	22,621	43.5	11,686	22.5	3,688	171.9

The *mortality statistics* in this Report are presented in considerable detail as to causes of death for the various nationalities in conjunction with sex in fifteen age groups. Other tabular statements show the seasonal distribution of births and deaths.

Maternity and Child Welfare Work—Dr Muriel CLARK, Lady Medical Officer continues to contribute her admirable annual account of the work carried out in the supervision of Midwives and Infant Welfare Department. During the year 18 567 new babies were entered in the Clinic Registers—this figure presents 82.1 per cent. of the total annual births registered in the Municipality. Clinic consultation figures increased from 46,888 in 1936 to 50 623 in 1937—a striking testimony to the steadily increasing confidence of mothers in the work of the Clinics and of their growing tendency to seek advice and treatment. District Sisters and Staff Nurses paid 27 999 visits to the homes of patients and of this total 18 347 were first visits to newly confined or sick mothers—this increased volume of work was made possible by an additional appointment to the staff and the reorganization of the work into five districts in place of four as formerly. Health visitors also paid 114 700 home visits to patients during the year while Municipal midwives attended 1 654 confinements of poor mothers.

Dr Muriel Clark has much to say of the great prevalence of *avitaminosis* both in infants and mothers observing that *beriberi* continues to be a positive menace to the mothers and babies and cases are seen by us in ever increasing numbers. Provision has been made in the 1938 Budget for the allocation of funds for specialized work in connexion with syphilis and beriberi among mothers and babies attending the ante-natal clinics (see this *Bulletin* 1938 Supp. p. 181*). During the year 19 cases of *puerperal sepsis* were reported—all cases were carefully investigated but in none was the midwife the carrier of the infection. Fewer cases of *icterus neonatorum* were reported—in the 68 cases recorded and investigated it was found that in every case there had been no skilled attention at confinement.

Public Health Sanitation etc—The Department undertook and carried through successfully a considerable programme of works concerned with *malaria control*. These activities are described in great detail in a special section of the Report by Dr N. A. CANTON, Deputy Health Officer.

The whole of the *sewage* with the exception of that treated in house installations is dealt with at the Alexandra Road Disposal Works (see also this *Bulletin* 1937 Supp. p. 175* and 1938 Supp. p. 181*). Since the beginning of June 1937 all *night soil* has been collected at two stations and pumped through a pipe-line to the Disposal Works for separate treatment by a digestion process. Tabular statements are presented giving the averages and ranges of daily analyses of crude sewage and effluents from the Disposal Works. The sources of supply of *raw water* are the impounding reservoirs on Singapore Island and in Johore—the characters of the raw waters from these sources are very similar. Methods of treatment remain for all practical purposes unchanged (see this *Bulletin* 1935 Supp. pp. 168*–169*) and samples drawn from every part of the purification system are analysed daily—the results of these analyses are reproduced in a series of Tables in the Report under review.

With regard to housing Dr Hunter observes that "the greatest problem facing Singapore to-day is still insanitary housing specifically and an acute housing shortage generally" and proceeds to discuss the situation at some length. The *Improvement Trust* which was the direct result of the recommendations of the Housing Commission of 1918 is sadly hampered by the limitations of the objects on which its available funds may be expended, and by an Ordinance that has been legally assailed with success on almost every section of consequence. Dr Hunter urges that if the Trust or other responsible body cannot be given wider powers and the finance to undertake new housing on a more extensive scale and the Municipal Ordinance amended to ensure that all new buildings shall conform to prescribed sanitary standards, the need for a new Housing Commission is urgent.

The *Inspector of Foods and Markets* contributes his usual Annual Report on the Municipal Markets and the inspection of foodstuffs sold in them and in the town generally. This Report describes the year's work in great detail (see this *Bulletin* 1938 Supp. p. 181*). In another section the Municipal Analyst deals with the examination and findings recorded of 2,162 samples submitted by the Health Department of the total 1,014 samples were examined in connexion with the sale of *Food and Drugs Ordinance* and of these 460 were samples of milk and milk products.

Hospitals, Dispensaries, etc.—In the Annual Report of Dr C. C. B. Gilmour, Medical Superintendent of the Middleton Hospital, it is stated that during the year under review 1,324 patients were admitted, 1,360 treated, 1,246 were discharged, and 61 died. The diseases responsible for the majority of admissions were *chickenpox* 709 cases, *mumps* 206 and *dysentery* 170. As regards the nationalities of patients admitted, 820 were Indians, 344 Chinese, 67 Europeans and 85 Malays. 287 of these were Municipal employees and 1,174 school-children.

The records of morbidity experiences *etc.* 1937 contain no particularly outstanding feature. The year was free from the three dangerous infectious diseases, *smallpox*, *cholera* and *plague*. During the year 18,999 vaccinations were performed and of these 15,881 were done by Municipal Vaccinators. Routine rat trapping was carried out continuously. 3,381 rats were destroyed and examined at the Bacteriological Laboratory but none was found to be infected with *P. pestis*. The flea index per live rat was 1.81 and in this connexion it is observed that this so far unexplained scarcity of insect life on our local rat constitutes the greatest single protective factor in our freedom from *plague*.

Of the 217 cases of *dysentery* reported 207 were admitted to Hospital and 42 died. Total deaths ascribed to this disease 57. It is believed that many more cases occurred than were notified, for the affection is regarded lightly, especially by lower class Chinese parents (see this *Bulletin* 1938 Supp. p. 182*). Dr Gilmour of the Middleton Hospital is of the opinion that the immunization of all infants should be seriously considered, and that this could be carried out by the Infant Welfare Branch just when the infants are coming off the register at the end of the first year of life. An attempt on a small scale is being tried to discover the reaction of parents towards the operation. At the Laboratory, *C. dysenteriae* was isolated in 461 out of 2,235 specimens examined.

Tuberculosis has been deleted from the list of notifiable diseases—this action having been taken without any consultation with the Medical Department. Despite the lack of facilities for dealing adequately with cases of the disease it is felt that the disinfection of houses and cubicles which followed notification was of some value in that it served to impress the public with the knowledge that tuberculosis was an infectious disease. No cases were admitted to the Middleton Hospital but total deaths due to this cause in the Municipality were distributed as follows —

Nationality	Deaths due to Tuberculosis		
	Respiratory	Other Forms	All Forms
Europeans	1	2	3
Eurasians	15	—	15
Chinese	1 085	152	1,237
Malaya	104	7	111
Indians	82	11	93
Others	15	1	16
Totals	1,302	173	1 475

Bronchitis caused the deaths of 244 people *broncho-pneumonia* 1 202 and *pneumonia* 542 during the year under review

Notifications of *enteric fever* totalled 227 five of these related to paratyphoid fever. Seventy three deaths were ascribed to *typhoid* and 1 to paratyphoid fever. Dr Hunter again comments upon the insanitary activities of the itinerant hawker who is responsible for a large share of this preventable disease, and observes of the contemplated new Food and Drugs Regulations designed to tighten up control of the peripatetic food hawker. These regulations are still on the stocks! As regards the mortality due to *dysentery* the following details are taken from tabulated returns —

Nationality	Deaths due to Dysentery			
	Amoebic	Bacillary	Unspecified	Total
Europeans	—	—	—	—
Eurasians	1	1	—	2
Chinese	55	40	77	172
Malaya	—	—	10	10
Indians	3	4	5	12
Others	4	—	—	4
Totals	63	45	92	200

Anti mosquito work is discussed at some length (see *Public Health* above) but there is no specific mention of the incidence of *malaria* though mortality returns ascribe 428 deaths to this cause. At the Bacteriological Laboratory where 5,925 blood films were examined 11.2 per cent were positive with *malaria* parasites the distribution of types of infection being *benign tertian* 392 *subtertian* 268 *mixed* infections 5 and *quartan* 1. Eight cases of *typhus fever* were notified

(1937)

hospitals exclusively reserved for female patients. The Report under review observes "The number of maternity cases admitted to Government hospitals was 7,522" but according to the Hospital Returns there were 7,793 cases of normal labour, 364 abnormal labour cases, a further 72 other cases associated with childbirth, and a large number of other cases included in the group *Conditions arising in Pregnancy etc.* At the Chinese Maternity Hospitals at Kuala Lumpur, Ipoh and Seremban 7,036 deliveries were recorded during the year. Particulars are not available for the Chinese maternity hospitals in the smaller towns.

The training of midwives in Government and Chinese Hospitals was continued as previously described (see this *Bulletin* 1933 Supp. p. 163*).

Infant Welfare Work continues to expand: there are 5 centres in Perak, 5 in Selangor (the 1933 Report said 9), 1 in Negri Sembilan and 1 in Pahang. Midwives practising in the towns are registered and supervised from these centres. *District visiting* has become a prominent feature of ante-natal and infant welfare work in all areas.

School Hygiene—Regular inspections of school premises and examinations of school-children continued to be carried out. During the year 58,920 children were medically examined and the following defects (in percentages) for each State recorded—

Item	Perak	Selangor	Negri Sembilan	Pahang
Dental defects	25.7	29.7	66.6	50.0
Skin diseases	4.0	8.8	7.2	6.9
Eye defects	0.7	0.9	4.4	0.3
Enlarged spleens	6.3	15.0	12.4	8.9
Pediculosis	— 0	4.7	15.8	0.3

The Dental Surgeon, Selangor, continued to visit the neighbouring States of Negri Sembilan and Pahang; a Dental Surgeon was appointed for work in Perak, and a Lady Medical and Dental Officer in Klang undertook the dental care of school-children in the coastal district of Selangor.

Public Health Sanitation etc.—Though by comparison with 1936 experience the crude death rate in 1937 rose only by 0.7 to 19.9 per mille, the Report observes that the public health "was not as satisfactory as in previous years." The mortality rate showed no striking change but the numbers of in-patients treated in Government Hospitals showed an increase of over 17 per cent. The passing of the *Anti-malaria Enactment* during the year empowers the Health Authority to issue orders for dealing with mosquito breeding places in any area.

There is little to add to previous descriptions of methods of *sewage and refuse disposal* except to say that in rural areas bored-hole latrines are increasing in number in villages and on estates. *Water supplies* are generally satisfactory. Village supplies are being improved: two purification plants have been erected in Perak, and in the lower reaches of the Perak River tanks are filled once a week with purified water conveyed by water-boat. The demolition of *insanitary houses and slums* continued to be systematically carried out in the large towns.

plans for new buildings must be approved by the Town Planning Committees and Health Officers in the various district areas.

Estates and Mines continued to be regularly visited by Health Officers. On estates progress is reported in the housing of labourers, provision of water supplies and general sanitation. Many of the larger estates have their own visiting medical practitioners but on the mines it is said that the supervision of health and sanitation is not so thorough and on the smaller mines in particular health supervision is difficult. Labourers employed by Government Departments receive the attention of Officers of the Health Branch while *Railway Sanitation* is dealt with by the Railway Health Officer (seconded from the Malayan Medical Service) and his staff.

The manufacture and sale of *foods and drinks* was closely supervised by the Health Department and Sanitary Board staffs. The usual measures were taken to spread *knowledge of hygiene and sanitation* special attention being devoted to kampong communities.

The training of Sanitary Personnel was continued. Probationer Sanitary Inspectors receive preliminary instruction from Health Officers and special facilities are provided in Singapore for candidates wishing to sit for the certificate of the Royal Sanitary Institute London.

Port Health Work—During the year 2 188 ocean-going vessels entered and cleared Port Swettenham and in addition clearances of local vessels (exclusive of native craft) numbered 728. The Port Health Authorities dealt with 137 763 passengers and 99 028 members of ships crews. 49 vessels arrived from infected ports and 55 645 immigrants and deck passengers were admitted to the Quarantine Station where they were examined for signs of leprosy, evidence of recent vaccination, helminthic infections, etc. 187 cases of leprosy were discovered and these were repatriated, 11 064 persons were vaccinated, more than half the immigrants were found to be infected with worms and anthelmintic treatment was given to all. To the Quarantine Hospitals 1 090 patients were admitted and 38 died.

Hospitals Dispensaries—The number of in patients dealt with at the various hospitals shows a large increase over the records for the preceding year. the relevant hospital data are as follows—

State	Hospitals	Beds	Admissions	Deaths	Out patients
Perak	18	2,418	50,893	3 874	104 404
Selangor	7	1 470	29 194	2,249	75 343
Negeri Sembilan	6	878	18,815	1,385	56 040
Pahang	8	661	16,996	988	73 837
Totals	37	5,527	115 893	8 494	309 624

Of the 115,893 in patients mentioned above 41,316 were Chinese 61 262 Indians 10 791 Malays and 2,529 Others.

[Three different statements of hospital admissions and deaths appear in the Report. one says 116 712 admissions with 8 469 deaths, the next 115 893 and 8 494 deaths and the third 121 929 admissions with 8 497 deaths.]

(1937)

In addition to the out patients treated at hospitals a large number were treated at stationary and travelling dispensaries, the numbers so dealt with exclusive of those treated at Infant Welfare Centres special clinics etc., were as follows —

Treatment Unit	Perak	Selangor	Negeri Sembilan	Pahang
Sanitary Dispensaries	86,416	107,365	23,092	11,680
Travelling Dispensaries	—	54,684	31,814	—
Road	69,785	—	—	30,331
River	12,661	—	—	970

Sections of the Report under review briefly comment upon the work of such specialist services as *Ophthalmology Radiology Dental Surgery* etc.

The prevailing diseases among hospital in-patients were *malaria respiratory ailments venereal diseases and intestinal affections* some of these causes are briefly referred to in the notes which follow.

A somewhat serious increase in *malaria* incidence was a feature of 1937 health experience and it is said "over 35 000 cases were admitted to hospitals (Hospital Returns show 24 778 and in addition 15,225 patients were treated in Estate Hospitals) and the Malaria Advisory Board's "Index of Malaria" which represents incidence in 1933 as 100 was 154 in 1937. The distribution of types of infection among 24 778 hospital in-patients was *benign tertian* 8 040 *quartan* 381 *subtertian* 12,715 *malarial cachexia* 2,131 *mixed infections* 714 *unclassified* 2,772, and *blackwater fever* 23.

In the Federated Malay States as a whole 1 144 deaths were registered as due to *malaria* but no less than 13 030 deaths were ascribed to *Fever of undefined origin*.

Meteorological conditions undoubtedly were responsible for some part of the increase of *malaria* but other factors were (a) the arrival of large numbers of non-immune labourers for work on mines and estates, and (b) the creation of new mosquito breeding places consequent upon replanting activities on rubber estates.

At Hospital Laboratories in the four States 296,235 blood films from 150,373 patients were examined for the presence of *malaria* parasites positive findings were, *subtertian* 17,305 *benign tertian* 11,509 *quartan* 862, and *mixed infections* 1 107. The Malaria Research Division continued the investigation into the relative therapeutic values of *atebrin totaquina, quinine* and certain proprietary remedies.

The dangerous infectious diseases mentioned in the Report and treated in hospitals include 208 cases of *diphtheria* with 62 deaths (294 notifications and 72 deaths in the four States) 211 cases of *tropical typhus* causing 16 deaths—under this title are included 122 cases of Japanese River Fever and 7 deaths. 13 cases of *cerebrospinal meningitis* with 12 deaths 10 cases of *acute poliomyelitis* with 3 deaths, and 183 cases of *tetanus* with 148 deaths. with regard to the latter title it may be noted that no fewer than 113 of the cases and 101 of the deaths are referable to newly-born children.

The numbers of admissions to hospitals and deaths in the four States due to *enteric fever* have steadily increased during the past four

years Of the 336 hospital cases resulting in 69 deaths 330 of the cases and 68 of the deaths were *Bact typhosum* and the remainder *Bact paratyphosum* infections *Dysentery* and *diarrhoea* also cause a progressively increasing number of cases and deaths each year without any apparent explanation to account for these increases though possibly the arrival of new immigrants from India may be an important factor During the year under review hospital in patients treated for *dysentery* numbered 1,537 distributed as to 900 *amoebic* 385 *bacillary* and 252 undefined cases there were 186 deaths In patients suffering from *diarrhoea* and *enteritis* totalled 2 566 and 584 died 912 of the cases and 400 of the deaths occurred among children under two years of age At the Hospital Laboratories where the stools of 120,842 patients were examined 1 135 specimens were positive with *E histolytica*

Deaths from *beriberi* in the four States numbered 319 and of these 131 occurred in Selangor Hospital in patients treated for this cause numbered 584 and 59 of them died It is now being recognized that *beriberi* exists amongst the Malay population to a greater extent than has hitherto been realized in areas where rice is not grown

In the Federated Malay States as a whole 1 413 deaths were ascribed to *tuberculosis* (all forms) Patients suffering from various forms of the disease and treated in hospitals numbered 2,317 and 897 died while of these 1 994 of the cases and 791 of the deaths were due to the *pulmonary* form of the disease The disease is most prevalent among the Chinese An investigation of the tuberculin reaction of school-children has been commenced *Pneumonia* is another cause responsible for considerable sickness and mortality 3 624 in patients were treated and 1 707 died There were also 3,924 cases of *bronchitis* with 120 deaths A year ago it was observed that *helminthic diseases* were a serious cause of disability During the year under review 1 407 in patients were treated for *ascariasis* 926 for *ankylostomiasis* 23 for *filariasis* 11 for *dracontiasis* and 74 for other helminthic infections. At the Hospital Laboratories where 189 148 examinations of faecal specimens were carried out 29,384 were positive for *Ascaris* and 11,271 for *ankylostome* ova.

Leprosy is discussed at some length in a special section of the Report To the Sungai Buloh Settlement there were 430 new admissions 221 re admissions 214 patients absconded 134 were discharged and 121 died, leaving at the end of the year 1 937 patients in residence Of the 1937 inmates 1 409 were men 382 were women and 146 were children while the racial distribution reads Chinese 1 459 Indians 326 Malays 139 and Others 13 The old Leper Asylum Kuala Lumpur accommodates a diminishing number of chronic incurable lepers who are opium smokers at the end of the year there were 183 of these The unsatisfactory classification of *leprosy* into cutaneous and neural provoked a good deal of research work in connexion with the recognition of the intermediate types and it has been established that there is an insensible gradation between tuberculoid and cutaneous *leprosy* A new and interesting type which appears to be unknown elsewhere is described as acute ulcerative tuberculoid *leprosy* In view of the absence of any standard description of the treatment of tuberculoid *leprosy* experiments were undertaken during the year with the object of discovering what specific treatment would prove of

(1937).

most value the most satisfactory results were obtained by subcutaneous injections of hydnocarpus oil twice a week, in doses equivalent to 1 cc. per 10 lbs. of body weight.

During the year several members of the Health Department Staff attended a course in the early diagnosis of leprosy at the Sungai Buloh Settlement.

There was a further increase in the number of cases of venereal diseases treated in hospitals. The figures for in-patients only totalled 4,935 and these included 1,628 cases of syphilis, 2,221 of gonorrhoeal infections, 851 of soft chancres and 218 of tropical bubo. In another section of the Report under the heading "Social Hygiene" the following details are supplied of new cases treated at hospitals and clinics during 1937 —

Race	Syphilis	Gonorrhoea	Soft Chancres	Totals
Chinese	4,819	3,058	846	8,723
Tamils	2,899	2,372	1,031	6,212
Malays	1,477	946	114	2,537
Sikhs	363	327	103	793
Erramans	45	51	21	115
Europeans	9	59	9	77
Others	221	153	23	396
Totals	9,741	6,965	2,147	18,853

To the Central Mental Hospital the number of admissions during the year—1,225—established a record. The rapid increases in the numbers of admissions to this institution in recent years is described as alarming. Considerably fewer patients were discharged during the year 750 as compared with 863 in 1936 and at the end of the year there were 2,882 patients in the hospital.

Other diseases mentioned include the following. No case of *Plague* or *Cholera* has been reported since 1923. During the year under review no case of *smallpox* was notified. Routine vaccination work was continued and 108,285 vaccinations performed. The incidence of *anaemia* again showed an increase with 2,019 in-patient cases and 311 deaths. 1,328 of the cases and 200 of the deaths were due to secondary anaemia characterizing the terminal stages of such diseases as malaria and *ankylostomiasis*. For *ulcers* 2,973 patients were treated.

Scientific—The results of routine examinations carried out at the Hospital Laboratories have been the subject of brief mention in the preceding notes. At the *Institute for Medical Research* periods of considerable pressure characterized the work of divisions concerned with the preparation of prophylactic biological products. The arrival of cases of *cholera* among immigrants from India and infected ships from China brought heavy demands for *cholera* vaccine from the Quarantine Stations and as a precautionary measure it was deemed advisable to increase the stocks of that vaccine. Later in the year cases of *canine rabies* were reported in Singapore supplies of canine anti-rabies vaccine were prepared, and all dogs on the Island were subjected to prophylactic vaccination. Despite these interruptions, considerable progress is reported in various research investigations.

Mention has been made of the results of therapeutic tests of certain drugs carried out in the Malaria Research Division (see *Malaria* above) this Division also reports the trapping of a number of infected *An. notumbrosus* a jungle swamp breeder and a species which must be added to the already long list of local vectors of malaria. The *filariasis* investigations were continued (see this *Bulletin* 1938 Supp p 168*) Infestation is widespread among the riverine population of Perak the majority due to *Microfilaria malayi*. Entomological investigations indicate that *Mansonia* mosquitoes are the principal local vectors of *Microfilaria malayi*.

Financial—Total expenditure on Medical Department Services in the Federated Malay States amounted to \$4 155 579 in 1937 and in addition the Public Works Department expended \$198 143 on new buildings for hospitals etc and \$79 606 on the maintenance of buildings.

MALAY STATES NOT INCLUDED IN THE FEDERATION

Johore (1937)

The State of Johore lies at the southern extremity of the Malay Peninsula to the north is Pahang, to the north west Negri Sembilan and Malacca, on the west the Straits of Malacca, on the south the Strait north of Singapore and on the east the China Sea. The area of the State is about 7 320 sq miles, almost exactly that of Wales.

Introductory—The general make-up of the Annual Report has been subjected to complete revision with successful results (see this *Bulletin* 1937 Supp p 183* and 1938 Supp. p 184*) The present 8vo volume replaces the former cumbersome foolscap publication the interpretative text is ample and informative large numbers of excellent photographs illustrate the various amenities provided in the interests of public health, and finally the tabular matter is so concisely and conveniently arranged that a considerable economy of space has been effected.

Vital Statistics—The relevant facts read as follows —

Race	Estimated Population	Births	Birth Rate	Deaths	Death Rate	Infant Deaths	I.M.R.
Europeans	930	17	18.3	3	3.2	0	—
Eurasians	330	6	15.8	2	5.3	1	166.6
Malaynans	287,500	11,997	41.8	5,852	21.4	2,143	178.6
Chinese	268,300	12,882	48.0	5,460	20.4	1,592	123.6
Indians	7,600	2,033	28.0	1,617	22.3	404	193.7
Others	3,800	96	25.2	48	12.6	14	145.6
Totals	613 510	27 031	44.1	12,982	21.1	4 154	153.6

The draft Bill of a new *Registration of Births and Deaths Enactment* was published in 1937 no details are supplied.

European Officials resident numbered 134 no invalidings or deaths were recorded. Of resident *Asiatic Officials* there were 7 145 and of these 62 were invalided and 13 died.

Estate Populations—On the 551 registered estates in Johore the monthly average of labourers employed with their dependants was 88,931 during the year 1,211 deaths occurred among estate populations.

Maternity and Child Welfare Work—Maternity cases admitted to and delivered in Government Hospitals numbered 3 026 and among these 57 maternal deaths were recorded.

There are now four *Women and Children's Clinics* for a new clinic was opened at Segamat in October 1937. The work carried out at each of these Clinics is described in detail for present purposes the following summary must suffice. During the year 6,984 women attended for ante-natal examinations, 716 maternity cases were conducted by clinic staffs, and 399 clinic cases were conducted by certified non-Government midwives. In towns where no clinics are established Government Deputy or Assistant Medical Officers assisted by Government or private midwives saw 370 ante-natal cases, conducted 172 confinements and treated 46 post-natal cases.

The 23 733 new patients attending the four clinics during 1937 included 12,396 infants and children. In addition 106,565 visits were made to patients in their own homes by Lady Medical Officers, Maternity Nurses and Midwives.

There were 30 *pupil midwives in training* during the year and 6 of these passed the required examinations and were granted certificates, authorizing them to practise in the State. In addition 12 new midwives were granted similar authority. Arrangements have been made to station subsidized midwives in the *kampungs* to give midwifery assistance to village women. There are four such midwives at present.

School Hygiene—Five English and fifty-five Malay Boys' Schools were visited during the year and 1,643 pupils at the former and 6 044 at the latter schools were medically examined. The general health conditions, cleanliness, etc. of pupils were satisfactory. Thirteen Malay Girls' Schools were inspected and 1,246 pupils examined. Enlarged tonsils and dental defects were the principal conditions noted. Arrangements are made throughout the State for the treatment of school-children during the year 3 785 pupils were treated at Out-door Dispensaries, and 38 690 by the Motor Travelling Dispensaries.

A new *Dental Clinic* for the treatment of school-children was opened at Batu Pahat (see this *Bulletin* 1938 Supp. p. 185*) and steps are being taken to establish similar clinics in other localities. During the year 4 649 pupils were examined and 3 717 were found to require treatment. A striking feature is said to be the growth in the appreciation of dental treatment by Malay girls.

Public Health Sanitation etc.—The newly created *State Medical Board* functioned throughout the year and proved of value in keeping the Department in touch with public opinion and the medical needs of the various districts of the State (see this *Bulletin* 1938 Supp., p. 185*). About 16 per cent. of the total population in Johore live in the *Town Board* areas. For each of these areas a brief account of public health activities is provided and such matters as *conservancy water supplies, housing markets* etc., are discussed. Only meagre references are made to *rural sanitation*.

Anti-malarial work continued to be carried out as usual under the authority of the *Anti Malaria Board* the work carried out by the three Divisional Health Officers and their staffs is described in detail but

calls for no special comment (see this *Bulletin* 1938 Supp pp 185*-186*)

Under the heading of *Estate Hygiene* it is reported that 826 visits were paid by Health Officers and their staffs to the 351 registered estates in the State recommendations made for the improvement of lines water supplies latrines, etc. were in most cases carried out

Port Health Work—During the year 80 steamers called at Johore ports and 11 were examined no cases of infectious diseases were reported Vessels engaged in the local coasting trade are not inspected

Hospitals Dispensaries etc—A very considerable building programme is in progress and a large number of buildings and extensions of various kinds were either completed or under construction during the year The following Table summarizes the details of bed accommodation and volume of work dealt with in 1937 at the 15 hospitals in the State —

Institution	No of Beds	Patients Admitted	Patients Treated	Hospital Deaths
Johore Bahru General Hospital	630	11 451	11,801	918
Muar " "	280	6 550	6 744	353
Tangkak " "	128	3 011	3 123	129
Batu Pahat	185	3 982	4 105	217
Kota Tinggi " "	140	2,661	2,738	121
Segamat " "	182	5 309	5 479	347
Kluang " "	204	4,859	5 145	315
Mering	60	1 028	1 089	56
Pontian Rechul " "	68	1 194	1,219	33
Two Military Forces Hospitals	24	418	423	—
Mental Hospital	1 104	206	712	40
Lepor Asylum	250	114	359	14
Two Gaol Hospitals	44	259	277	5
Totals, 15 Institutions	3,270	41 142	43,234	2,350

There appear to be 17 *Out-door Dispensaries* 5 *Motor Travelling Dispensaries* and one *Muar River Motor Boat Dispensary* (these are exclusive of the numerous *Special Clinics* in the State) The work at these and other centres may be summarized as follows —

Item	New Cases	Total Treatments
17 Out-door Dispensaries	84 364	133 636
5 Motor Travelling Dispensaries	56 636	120,875
1 Motor Boat Dispensary	5 888	8 574
All other centres	81 912	85,557
Totals	258,800	348 642

The *training of Nurses* was continued throughout the year at the Johore Bahru General Hospital during the year 17 candidates completed the course and were posted as Probationer Nurses. A new hostel for nurses is under construction and approaches completion.

Courses of training for *Hospital Dressers* are also provided at this Hospital and at the Muar Government Hospital and examinations are held annually.

There are 40 *Estate Hospitals* in the State. The only details supplied for these institutions appear to be the numbers of cases treated of the 12 more important diseases of these there were 113,597 and 1 211 deaths.

The notes which follow briefly refer to some of the more outstanding items of morbidity experience commented upon in the Report under review.

No cases of *plague cholera* or *smallpox* were reported during the year. Over ten thousand rats were examined but none was found infected with *P. pestis*. During the year 24,559 anti-smallpox vaccinations were performed, 16,593 of these by the five special Government Travelling Vaccinators. Dangerous infectious diseases notified included the following —

Of fevers of the *enterica* group 301 cases with 70 deaths. With the exception of 20 non-fatal cases, all were treated in Government Hospitals. There were recorded 641 cases of *dysentery* with 103 deaths and 629 cases of *diarrhoea and enteritis* with 112 deaths all were treated in Government Hospitals. In *Estate Hospitals* 1,047 cases of *dysentery* with 33 deaths and 2,966 cases of *diarrhoea* with 42 deaths were recorded.

For purposes of convenience and economy of space certain other infectious diseases notified during the year can be summarized as follows —

Disease	Treated in Hospitals	Deaths	Treated outside Hospitals
Tropical typhus	3	0	—
Japanese river fever	1	0	—
Scarlet fever	1	0	1 non-fatal case
Cerebrospinal fever	10	8	1 fatal case
Diphtheria	63	7	9 non-fatal cases
Chickenpox	106	11	20 " " "
Measles	606	1	559 " " "
Erysipelas	17	5	3 " " "
Acute polyomyelitis	2	0	—
Encephalitis lethargica	1	1	—

Among the most prevalent diseases treated in Government Hospitals, malaria heads the list with 7 785 microscopically diagnosed cases, with 268 deaths. 1,333 cases of *unspecified malaria* with 44 deaths, while *unspecified fevers* accounted for 265 cases and 7 deaths.

In *Estate Hospitals* 12,391 cases of *malaria* with 159 deaths, and 17 123 cases of *fever unspecified* with 23 deaths were dealt with.

At Government Hospital Laboratories and Dispensaries 58,558 blood films were examined for the presence of malaria parasites and 9,299 gave positive findings. Among the positives *subtertian* infections accounted for 49.4 per cent. *benign tertian* 31.4 *mixed infections* 18.0 and *quartan* 1.2 per cent.

Of *pulmonary tuberculosis* 693 cases were treated in Government Hospitals with 277 deaths, while deaths in the State due to this cause

totalled 558. The usual routine medical examinations of Government officers for signs of pulmonary tuberculosis were carried out and 2,688 persons were examined during the year. Hospital cases of pneumonia numbered 948 and deaths 399. In the State as a whole 950 deaths were registered as due to pneumonia.

In *Estate Hospitals* there were recorded 128 cases of pulmonary tuberculosis with 17 deaths and 1,032 cases of pneumonia with 262 deaths.

Beriberi was the registered cause of death of 254 persons during the year under review. For this cause 372 patients were treated in Government Hospitals and 33 died while in Estate Hospitals 325 cases were treated and 14 deaths recorded.

To the *Leper Asylum*, Johore Bahru, 114 patients were admitted during the year, 14 died, 18 were discharged and 62 absconded, leaving at the end of the year 267 patients still on the books of this institution.

Other diseases mentioned in the Report under review included the following —

Item	Government Cases	Hospitals Deaths	Estate Cases	Hospitals Deaths	Deaths registered in the State
Violence (all forms)	2,097	39	7	7	298
Ankylostomiasis	1,256	10	5,414	7	18
Ulcers	1,002	0	4,241	2	7
Veneral diseases	1,332	8	502	3	37
Yaws	45	0	7	7	7
Influenza	2,074	10	7	7	8

Scientific—At the Laboratories of the General Hospital, Johore Bahru and the Government Hospital, Muar, 75,291 bacteriological and pathological examinations were made during the year. These included the examination of 33,423 blood films, 6,642 Wassermann and Kahn reactions, 2,750 Widal's and other agglutinations, 2,926 examinations of sputum and 3,490 examinations of specimens of urine. In addition a large number of specimens were examined at other Hospitals and Dispensaries in the State, among them 25,133 blood films, 3,365 samples of sputum smears etc. and 19,095 faecal specimens. Details of this work are set out in a series of tabular statements together with the findings recorded.

Financial—Total expenditure on Medical Department services during 1937 amounted to \$1,555,628, a sum which represents 7.8 per cent. of the total revenue of the State during the same year.

Kedah (1937)

Kedah, a Malay State under British protection, lies on the west coast of the Malay Peninsula. It is bordered on the interior by Siam and Perak, and includes the island of Langkawi and a number of smaller islands to the south. The mainland is about 105 miles long and about 65 miles wide at its widest part. Its area, including the Langkawi group of islands, is about 3 618 sq. miles.

Vital Statistics—The data relating to population, births, deaths etc. continue to be presented in great detail in a number of tabular statements (see comments below). As mentioned in the previous issue of this *Supplement* deaths in early life appear to be a feature of Kedah mortality experience—during the year under review approximately 50 per cent. of the total deaths registered occurred at ages 0-20 years, and no less than 45 per cent. in the 0-5 age-group alone. The principal facts for the State as a whole read as follows—

Race	Population	Births	Birth Rate	Deaths	Death Rate	Infant Deaths	I.M.R.
Malays	319,200	11,654	36.5	6,265	19.6	1,480	127
Chinese	83,472	3,748	43.8	1,914	22.4	505	133
Indians	64,402	2,007	35.6	1,407	24.9	432	215
Non-Asiatics	631	7	11.1	1	1.6	—	—
Others	13,010	243	11.4	191	14.9	21	85
Totals	474,776	17,664	37.2	9,781	20.6	2,436	136

As regards *Estate Populations* the relevant data are set out in similar fashion for purposes of comparison, viz.—

(a) European Holdings.

Race	Estate Population	Births	Birth Rate	Deaths	Death Rate	I.M.R.
Malays	5,769	69	11.0	31	3.6	203
Chinese	1,805	31	17.3	13	7.2	129
Indians	36,112	1,359	38.5	903	25.0	251
Javanese	61	—	—	—	—	—
Others	108	1	9.3	1	9.2	—
Totals	43,842	1,490	33.9	938	16.8	255

(b) Asiatic Holdings.

Race	Estate Population	Births	Birth Rate	Deaths	Death Rate	I.M.R.
Malays	7,559	25	3.3	17	2.3	160
Chinese	3,091	15	4.8	9	2.9	8.7
Indians	2,287	23	12.2	26	11.4	107
Javanese	44	—	—	—	—	—
Others	80	—	—	—	—	—
Totals	13,061	63	5.2	52	3.98	273.8 (see below)

With regard to the above data relating to population on Estates it should be added that though numerous tabulations of facts are supplied some of the calculated rates appear to be incorrect and in other cases discrepancies are noted between different statements relating to similar facts. For example in Table XXI.B the crude birth rate on Asiatic Holdings is given as 20.4 per 1 000 but the 68 births related to a population of 13 061 give a birth rate of 5.2 per 1 000. In Table V.D dealing with Asiatic mortality data the crude death rate is published at 16.5 per 1 000 but 52 deaths related to a population of 13 061 give a death rate of 3.9 per 1 000. Table XI.A gives the deaths on Asiatic Holdings as 23 but Table XVI records them as numbering 52. The infant mortality rates on Asiatic Estates do not appear to be convincing—three specific rates are quoted in Table XXI.B as 160, 107 and 67 respectively yet the gross rate for all nationalities is given as 273.8 per 1 000 births. As a matter of fact on the basis of data supplied in Table XI.A the specific rates for Malays, Indians and Chinese are 200, 214 and 67 respectively and the rate for all communities 176 per 1 000 births. The Report observes: "Figures for Asiatic Estates are known to be inaccurate. This remark is presumed to relate to the raw data supplied from these sources and not to the arithmetic applied to the facts for the calculation of rates."

The usual statement dealing with the health of *European Officials* seems to have been omitted from the Report under review.

Maternity and Child Welfare Work—It is stated that though it is yet too early to seek the benefits resulting from the introduction of the *Kampong Midwifery Service* (see this *Bulletin* 1938 Supp. p. 189*) yet a most successful beginning has been made. The four locally trained midwives posted to kampongs will have an uphill fight before they completely overcome the conservatism of Malay women and succeed in combating the opposition of the old *bidans* but strenuous efforts are being made to surmount these and other difficulties. Four more midwives are to be posted to kampongs and four new pupils are to commence their training. In addition to the introduction of this service with a view to the improvement of midwifery practice the new *Midwives Enactment* aims at the control of midwifery by the establishment of a system of compulsory registration and organized supervision—so far the new law applies only to the three largest towns *viz.* Alor Star, Sungei Patani, and Kulim.

The work of the Lady Medical Officer in charge of Maternity and Child Welfare has again proved of immense value—the record of the year's work reads as follows—

Item	Women's and Children's Clinics		
	General Hospital	Town Dispensary	Other Dispensaries
First Visits	691	2,102	—
Subsequent Visits	761	3,309	—
Injections (for Yaws)	2,107	—	284

School Hygiene—The provisional approval of Government has been obtained sanctioning the appointment of an additional Assistant Health Officer primarily intended for general health work in North Kedah but concentrating his activities upon laying the foundations of a regular School Medical Inspection Service. During the year under review all Malay Vernacular Schools not visited in the preceding year were inspected in the course of these visits opportunities were used for giving brief talks on health matters to school-children. Various recommendations were made with a view to improving the sanitary conveniences of school premises and for remedying minor defects. Three Chinese schools were visited and inspected at the request of the Registrar of Schools. Chinese schools are not subject to the routine visits paid by the Medical Department. Upwards of 5,000 school children were examined in nine districts and 206 of them were found to have enlarged spleens spleen rates ranged from nil to 13.3.

As regards the volume of work dealt with in connexion with the School Medical Service it is noted that 39 Malay Vernacular Schools, and 4,690 school-children were inspected. 3 non-Government Chinese Schools and 189 children were inspected. The principal defects recorded during the medical examination of school-children may be summarized as follows—

Defects	Percentage of defects recorded in —	
	Malay Vernacular Schools	Non-Government Chinese Schools
Cases Class I	9.5	10.6
II	8.7	7.1
III	7.3	16.3
Scabies	5.9	4.7
Eye diseases	0.3	3.6
Enlarged spleen	4.1	1.2
Anaemia	1.9	2.4
Yaws	1.7	nil
Not vaccinated	2.1	5.9

Public Health Sanitation etc—The various increases in Departmental staff necessitated by the reorganization of Medical Services (see this *Bulletin* 1938 Supp p 190*) received the approval of Government. New services provided or contemplated are mentioned in appropriate sections of the present Summary. Malaria control work in the three principal towns continued along lines previously described in rural areas where anti-larval measures are impracticable, drug prophylaxis was continued.

In the nine Sanitary Board areas (see this *Bulletin* 1938 Supp p 190*) little has been done to improve methods of *sewage disposal*. Considerable attention was devoted to the improvement of *water supplies* during the year schemes envisage the provision of filtered and chlorinated supplies to all the large towns and extension of supplies to rural dwellers. These schemes can only be developed with the *gradualness of time*. As regards *housing and town planning* it is stated that in the larger towns considerable demolition of old and

insanitary houses was carried out during the year and that building layouts have been prepared for use in both large and small towns. Certain areas have been gazetted so that future building can be controlled.

Health conditions on estates mines etc continued to receive attention and the Health Board Scheme applicable to such properties functioned smoothly. All European Estates were visited at least once during the year but it is again noted that a large amount of extra work was entailed in the supervision of Asiatic Estates owing to the obstruction of the majority of owners. Improvement in housing conditions sewage disposal water supplies etc on various estates is recorded.

Quarantine restrictions were applied against the arrival of passengers and various commodities from Siam on account of cholera. Railway passengers subjected to routine inspection at Padang Besar numbered 12,756.

Hospitals Dispensaries etc—A considerable amount of building and general activity featured the year under review. The new schemes of work envisage the provision of a Dental Clinic and Tuberculosis Department at the General Hospital Alor Star provision of a Venereal Diseases Clinic as a branch of the Town Dispensary Alor Star new dispensaries in three areas structural additions to various hospitals etc.

Further extension of the chain of *kampung* dispensaries will ensure that the whole of the rice-growing population in North Kedah will shortly be provided for similar provision for the remoter areas of Central and South Kedah are also under consideration.

The *training of dressers* has now been brought into line with the schemes of work followed in the Straits Settlements and Federated Malay States. One dresser is to attend the Pharmacy course at the Singapore College of Medicine and one Health Inspector is attending the course of study leading up to the Diploma of the Royal Sanitary Institute.

As regards the volume of work dealt with at medical institutions providing for the needs of the general public and Government Officials, the following details have been extracted—

Hospital	In-patients			Out-patients		
	Beds	Treated	Died	New Cases	Re-visits	Totals
Alor Star	300	6 952	325	10,208	2,856	13 064
Sungei Patani	300	6 729	298	7 048	1 485	8,533
Baling	35	347	13	3 548	1 042	4,590
Kulim	210	4,678	290	9,399	2,444	11,843
Langkawi	70	498	23	3,230	501	3 731
Prison Sick Wards.						
Alor Star	7	129	—	1,291	4 891	6,282
Sungei Patani	7	—	—	120	698	818
Totals	915	19,531	889	34 844	14 017	48,861

5 Outdoor Dispensaries, Alor Star	31,501	14,649	46,150
1 Dispensary Sik (Central Kedah)	3,447	394	3,841
1 " " Bandar Bahru (S Kedah)	2,175	364	2,539
1 Padang Mambang (Langkawi)	70	48	516
4 Motor Travelling Dispensaries (1 each District)	20,783	2,738	23,521

The above details refer to State Hospitals. The medical requirements of the large labour forces on rubber estates are met by the Health Board organization hospitals maintained by the Health Board groups accommodate a total of 1063 beds. Each hospital has an outdoor dispensary. To Group Hospitals on European Estates 22,679 patients were admitted and 717 died, the corresponding figure for hospitals on Asiatic Estates being 855 and 20 respectively. The notes which follow summarize the principal references to morbidity experience during 1937 taken from the Report under review.

No case of cholera or plague was reported. The cholera epidemic in Siam gave rise to considerable anxiety and special precautionary measures were taken (see Quarantine above). No anti-plague measures have ever been enforced though rats are found in abundance in all centres of population.

Fifteen cases of smallpox were reported from South Kedah four of them terminating fatally. The first case (a Chinese woman newly arrived from China) all other cases occurred among Malays on a rubber estate) occurred on June 28th and the last on July 24th. A special vaccination campaign was instituted and 27 400 estate employees were vaccinated. Total vaccinations in the State numbered 41 333.

A prolonged epidemic of measles occurred chiefly on estates and among Indian labourers. The infection was introduced by newly arrived Indian labourers. Notified cases numbered 1443 and 28 deaths were ascribed to this cause. It is said that a considerably larger number of deaths occurred, certified as due to broncho-pneumonia which should have been assigned to measles. One fatal case (an Indian) of tropical typhus was recorded.

No epidemic of malaria was recorded, cases dealt with show an increase over the 1938 figures but fewer deaths were assigned to the disease, the recorded facts being 7 007 cases and 580 deaths. On the other hand deaths ascribed to "fevers unspecified" numbered 3 494, so that this title becomes responsible for 38 per cent. of the total deaths in the State due to all causes. As regards malaria on estates 13 164 cases of malaria and unspecified fever and 67 deaths were recorded. The majority—12,545—of the cases occurred on European estates but while on European holdings deaths due to malaria constituted 6 per cent. of the total deaths due to all causes, on Asiatic estates the corresponding ratio stood at 25 per cent. With regard to the data relating to Asiatic holdings the Report adds "It is impossible to consider these figures as of any value whatever for statistical purposes".

Of enteric fever 69 cases and 10 deaths were notified, and of dysentery and diarrhoea 520 cases with 370 deaths. It is also stated that in

State hospitals 244 patients were treated for dysentery and 16 died and in Group Hospitals (estate populations) 312 patients were admitted and 33 died [i.e. a total of 556 in patients alone treated for dysentery]

Mention has been made of the proposed establishment of a *Tuberculosis Department* at the General Hospital Alor Star (see *Hospitals* above) and with this aim in view Dr P. T. K. NAYAR, one of the Assistant Medical Officers attended an intensive course of study of modern methods of treatment of tuberculosis at the Brompton Hospital London. The scheme aims at the provision of a fully equipped and special ward and the establishment of an out patient clinic—a modest beginning has already been made to provide these special T.B. services. In patients at State Hospitals treated for *pulmonary tuberculosis* numbered 442 and 136 died for *other respiratory diseases* 694 cases and 71 deaths were recorded. To the Group Hospitals (estate populations) 473 patients were admitted suffering from *pneumonia* and 146 deaths were ascribed to this cause.

Other diseases—During the year in the State as a whole 301 deaths were registered as due to *ankylostomiasis* 647 cases were treated in State Hospitals with 13 deaths and 226 in Group Hospitals with 2 deaths. *Beriberi* caused the deaths of 144 persons 99 of these being Malays 31 Chinese and 11 Indians—no mention of the special investigation of lines of treatment is made (see this *Bulletin* 1938, Supp. p. 193*). *Kedah lepers* continue to be accommodated and treated at the four institutions outside the State—during the year 213 were under treatment 14 died and 16 absconded. In a special Appendix the new policy regarding the control of leprosy is discussed (see below *Scientific*). Deaths ascribed to *syphilis* numbered 29. A special *Veneral Diseases Clinic* is to be established in a room which is to be set aside for this purpose in the new Town Dispensary, Alor Star. The new *Dental Clinic* (see this *Bulletin* 1938, Supp. p. 190*) has functioned with success since its opening in October 1937—during the last three months of the year 215 new cases and 250 re-visits were recorded.

Scientific—Each of the five State Hospitals has its own branch laboratory and during the year 43,728 specimens were examined. At the Central Laboratory Sungai Patani, 7,413 specimens were examined but findings are not recorded.

Three special Reports appear as Appendices to the Report under review viz—

1. *A Health Survey of Langkawi Island* by Dr E. D. B. WOLFE who records the results of his examination of 2,800 persons the sanitary condition of the island etc.

2. *The New Policy regarding the Control of Leprosy* which aims at abolition of the former system of compulsory isolation by means which will induce sufferers to seek treatment voluntarily etc.

3. *Report of a case of Hydrophobia* by Dr R. SIVASAMBANDAN

Financial—Total expenditure on Medical Department services during 1937 amounted to \$551,225

Perlis (1937)

Perlis is the most northerly of the Malay States, lying on the west coast of the Malay Peninsula. It is bordered on the interior by Siam to the north and Kedah to the south, and has an area of about 318 sq miles.

Vital Statistics—It is stated that the registration of births and deaths will eventually be carried out by an Assistant Medical Officer trained by the Senior Health Officer Kedah. The relevant vital statistics for 1937 are shown in the following Table—

Nationality	Population	Births	Birth rate	Deaths	Death rate	Infant Deaths	L.M.R.
Europeans	7	—	—	—	—	—	—
Eurasians	8	—	—	—	—	—	—
Chinese	6,224	257	41.5	173	27.8	37	144
Malays	42,497	1,474	35.9	723	16.7	14	98
Indians	977	23	23.5	23	23.5	3	130
Others (mostly Siamese)	1,992	39	19.6	44	22.1	7	179
Total	52,703	1,793	34.0	963	18.3	189	105.4

[The Table on page 49 entitled "*Stillbirths according to Nationality and Sex*" actually presents *live* births with these distinctions 105 stillbirths were recorded.]

There were 3 resident *European Officials*. *Arabic Officials* resident numbered 300 with the same average number resident seven were invalided and two died.

The population of labourers and their dependants on *estates* totalled 436, distributed as to 361 Indians, 74 Malays and a single Chinese. Fifteen births and six deaths—all Indians—were recorded.

Maternity and Child Welfare Work—One of the midwives trained at Alor Star for the newly created *Kampung Midwifery Service* (see p 187* *supra* and this *Bulletin* 1938 Supp. p 184*) was duly posted to her kampong in Perlis and another pupil midwife has commenced her course of training. During the year 13 deaths were registered as due to diseases of pregnancy childbirth and the puerperal state. The Hospital midwife attended 4 labour cases in the homes of patients.

School Hygiene—For the first time all women teachers in Malay Vernacular Schools were medically examined by the Lady Medical Officer Kedah. Owing to the absence on leave during part of the year of the Assistant Medical Officer and of the Assistant Health Officer when attending a course of training in Kedah the volume of work accomplished was somewhat less than usual. Ten schools were inspected and 948 children medically examined, the principal findings being summarized as follows—*dental caries* 30.8 per cent. *enlarged spleens* 17.5 per cent. *anacida* 17.2 per cent. Only 0.1 per cent. were affected with yaws. 37 children received N.A.B. injections for the disease.

Public Health Sanitation etc.—The work of the Medical Department, Perlis is supervised by the State Surgeon Kedah (Dr J. PORTERLY).

who reports that the general health of the Perlis population during 1937 was good. Routine anti malarial measures continued to be carried out and it is hoped by better control and by anti larval and drug prophylaxis to reduce malaria incidence in the endemic areas in course of time. Methods of *sewage and refuse disposal* remain as previously described (see this *Bulletin* 1938 Supp p 194*). As regards *water supplies* these remain as described in the previous issue of this *Supplement* reference is again made to the proposed installation of a filter plant at Padang Besar (see this *Bulletin* 1938 Supp p 194*). Kaki Bukit still obtains its supply from sources liable to pollution the provision of safe supplies can only be met by the removal of the villages to a new site and this matter is receiving the attention of the authorities. Additions and improvements to market stalls are reported shops street stalls and hawkers are inspected at regular intervals and licences issued only when prescribed sanitary standards are maintained. Steps are being taken to deal with unsatisfactory itinerant hawkers. *Hospitals Dispensaries etc.*—New Buildings for the accommodation of certain members of Medical Department staff were completed and occupied and various additions made to existing buildings during the year. The medical institutions provided for in patient and out patient treatments remain as previously described (see this *Bulletin* 1938 Supp p 194*). At the General Hospital Kangar 1 707 in patients were dealt with and 89 deaths were recorded 36 of these deaths occurring within 48 hours of admission. 806 of the patients were Chinese 594 Indians and 288 Malays. Out patients treated at this Hospital numbered 5 443 and of these 3 286 were Malays 1 211 Indians and 887 were Chinese. [The racial proportions among in patients and out patients are striking. Among in patients Chinese head the list with 47 per cent. while only 17 per cent were Malays but among out patients the positions become reversed Malays 60 per cent Chinese 16 per cent.] The Outdoor Dispensary at Kaki Bukit dealt with 6 315 new cases and the Travelling Dispensary 411 cases (exclusive of those treated at Schools Coolie Lines etc.) In common with usual experience *malaria* and *fevers unspecified* were responsible for the largest proportions of the total deaths registered in Perlis during 1937—no less than 41 per cent of the deaths due to all causes appear under these two titles. Only 19 deaths were specifically assigned to *malaria* but 376 were due to *unspecified fevers*. Types of infection are not differentiated in the Hospital Returns but Hospital in patients treated for malaria numbered 457 and 10 died. among 4 872 blood films examined at the Hospital Laboratory Kangar 1 912 contained malaria parasites the percentages and types being *benign tertian* 51 4 *subtertian* 38 5 *mixed infections* 9 8 and *quartan* 0 3 per cent. Larval surveys indicated *A. barbrostris* as the most prevalent type followed in descending order by *A. kyrcanus* and *A. maculatus*. Twelve cases of *cerebrospinal fever* (all Chinese and mostly mining coolies) were notified. Eleven of the cases occurred in Kaki Bukit and its suburbs an insanitary area where conditions are ideal for the spread of such a disease. Ten of the cases were treated in Hospital with 5 deaths. Prompt and energetic action succeeded in suppressing the outbreak. No case of *typhus* or *smallpox* was reported. 1 796 vaccinations were performed.

Rabies—Seven persons were bitten by dogs actually suspected of being rabid—two were treated at Alor Star and Kangar Hospital. One refused treatment and died a month another reported at the Hospital a month after the bite and hydrophobia the day after admission and died. (This case is in the Kedah Report above.) The brains of two dogs at Institute for Medical Research Kuala Lumpur were declined for rabies.

Ten deaths were ascribed to *enteric fever* in the State and four cases of *typhoid fever* with one death and one fatal *paratyphoid* were treated in Hospital. Hospital patients in *dysentery* numbered 29 and 3 deaths were recorded. 14 of the were suffering from the amoebic type of the disease.

Forty-seven deaths were registered as due to *pulmonary* in cases admitted to Hospital numbered 54 and of these pulmonary 11 hospital deaths were recorded. Death *pneumonia* (all forms) in Perlis totalled 23. 44 cases with appear in the Hospital Returns.

Of the 4 Perlis *lepers* one was accommodated at the Pul Leper Settlement Straits Settlements and three at Sun P.S.S.

Other diseases mentioned in the Hospital Returns include *ankylostomiasis* 107 of *influenza* 54 of *ulcers* and 32 of

In the tabulated *causes of death* it is noted that 48 deaths, to "Demam Batak" a term which vaguely connotes *fever*.

Scarcity—Of the 8,205 specimens examined at the 14,872 were the blood-films already mentioned under preceding notes. As regards the remainder these included specimens 1,252 giving positive findings and 283 a specimen of which 32 contained *Mycobacterium tuberculosis*.

Financial—Expenditure on Medical Department for 1937 amounted to \$45,649 a sum which represents 6 per cent total revenue or 7 per cent of the total expenditure during the year under review.

Kelantan (1937)

The State of Kelantan is on the eastern side of the Malay Peninsula the north is the China Sea, on the south Pahang, on the east Trengganu and the China Sea, on the west Perak and Siamese Territory area is estimated at 6,720 sq. miles or rather less than the Yorkshire.

Vital Statistics—Births and deaths registration became only in July 1930. It is said that amongst Malays an registration is fairly complete but information is lacking births and deaths occurring among aboriginal hill districts of Ulu Kelantan, where many to be found. The relevant facts for the year follows—

Race	Estimated Population	Births	Birth Rate	Deaths	Death Rate	Infant Deaths	I.M.R.
Europeans	80	2	25.0	3	37.5	1	?
Malays	354,844	9,733	24.8	6,278	17.7	1,099	112.9
Chinese	27,034	698	25.8	396	14.6	64	91.7
Indians	10,401	225	21.6	200	19.2	48	213.3
Eurasians	72	0	—	2	27.8	0	0
Others	7,947	153	19.2	106	13.3	9	58.8
Totals	400,378	10,811	27.0	6,935	17.4	1,221	112.94

Deaths are classified in the Report under review by race age groups and by principal causes.

Of *European Officials* there were 28 resident with the same average number resident no invalidings or deaths were recorded. Of the 1,057 *non European Officials* with the same average number resident it is noted that eleven were invalided and five died during the year.

The total labour force with their dependants on *Estates* is returned as 6,135 but these are exclusive of *Estates* employing entirely Malay or Chinese labour as for such properties data are not reliable. Of the total of 6,135 persons 3,736 were Indians and their dependants and among this group 111 births and 109 deaths were recorded giving birth and death rates 29.7 and 29.2 respectively. There were 33 infant deaths so the infant mortality rate would be 297.2 per 1,000 registered births.

Maternity and Child Welfare Work—There is no special Maternity Hospital in the State but maternity beds are available at the Kota Bharu Hospital where however in spite of every effort services are not so far popular among Malay women. During the year 187 deliveries were recorded at the Hospital and of these 122 were Indian women, 59 were Chinese but only 1 was a Malay. Free facilities are provided for ante-natal treatment and delivery of women from *Estates*. Provision was made for the training of four Malay *bidans* but owing to the illiteracy of Malay women, difficulty was experienced in obtaining suitable candidates with the result that only one was selected to commence the course of training (see this *Bulletin* 1938 Supp. p. 197*).

An *Infant Welfare Centre* was started in premises acquired in the market area of Kota Bharu the work being under the charge of a part time Assistant Lady Medical Officer assisted by an Infant Welfare Nurse. This undertaking has made a most successful beginning the clinic is popular and attendances have steadily increased month by month. The Health Nurse after her daily work at the Clinic visits homes in Kota Bharu and in adjacent kampongs from which births have been reported. The record of the year's work shows that 1,343 visits were paid to newly-born infants 1,497 visits were paid to women (958 of these to Malay women) and 1,173 to children (of the latter 703 were Malay children).

School Hygiene—During the year 1 English and 42 Malay Vernacular Schools were inspected and 2,898 school-children medically examined. In towns the general sanitary condition of the schools is satisfactory and it is also said that in areas where anti-malarial measures are efficiently carried out spleen rates are low. Among

Rabies.—Seven persons were bitten by dogs actually rabid or suspected of being rabid two were treated at Alor Star and three at Kangar Hospital. One refused treatment and died a month later and another reported at the Hospital a month after the bite and developed hydrophobia the day after admission and died. (This case is referred to in the Kedah Report above.) The brains of two dogs sent to the Institute for Medical Research, Kuala Lumpur were declared positive for rabies.

Ten deaths were ascribed to *enteric fever* in the State as a whole. Four cases of *typhoid fever* with one death and one fatal case of *paratyphoid* were treated in Hospital. Hospital patients treated for *dysentery* numbered 29 and 3 deaths were recorded. 14 of the patients were suffering from the amoebic type of the disease.

Forty-seven deaths were registered as due to *pulmonary tuberculosis*. Cases admitted to Hospital numbered 54 and of these 51 were pulmonary. 11 hospital deaths were recorded. Deaths due to *pneumonia* (all forms) in Perlis totalled 23. 44 cases with 15 deaths appear in the Hospital Returns.

Of the 4 Perlis *lepers* one was accommodated at the Pulau Jerejak Leper Settlement Straits Settlements and three at Sungai Buloh, F.M.S.

Other diseases mentioned in the Hospital Returns include 82 cases of *oxyuriasis* 107 of *influenza* 54 of *ulcers* and 32 of *chickenpox*.

In the tabulated *causes of death* it is noted that 46 deaths are ascribed to *Demam Batok* a term which vaguely connotes *feverish cough*.

Scientific.—Of the 8,205 specimens examined at the Laboratory 4,872 were the blood-films already mentioned under *malaria* in the preceding notes. As regards the remainder these included 1,740 faecal specimens 1,252 giving positive findings and 283 specimens of sputum of which 32 contained *Mycobacterium tuberculosis*.

Financial.—Expenditure on Medical Department services during 1837 amounted to \$45,649 a sum which represents 6 per cent. of the total revenue or 7 per cent. of the total expenditure of the State during the year under review.

Kelantan (1837)

The State of Kelantan is on the eastern side of the Malay Peninsula. On the north is the China Sea, on the south Pahang, on the east Trengganu and the China Sea, on the west Perak and Siamese Territory. The area is estimated at 5,720 sq. miles, or rather less than that of Yorkshire.

Vital Statistics.—Births and deaths registration became compulsory only in July 1830. It is said that amongst Malays and other races registration is fairly complete but information is lacking regarding births and deaths occurring among inhabitants of the remote and hilly districts of Ulu Kelantan, where many aboriginal tribes are to be found. The relevant facts for the year under review read as follows:—

Race	Estimated Population	Births	Birth Rate	Deaths	Death Rate	Infant Deaths	I.M.R.
Europeans	80	2	25.0	3	37.5	1	?
Malays	334,844	9,733	24.8	6,278	17.7	1,099	112.9
Chinese	27,034	698	25.8	396	14.6	64	91.7
Indians	10,401	225	21.6	200	19.2	48	213.3
Eurasians	72	0		2	27.8	0	0
Others	7,947	153	18.2	106	13.3	9	58.8
Totals	400,378	10,811	27.0	6,985	17.4	1,221	112.44

Deaths are classified in the Report under review by race age groups and by principal causes.

Of *European Officials* there were 28 resident with the same average number resident no invalidings or deaths were recorded. Of the 1,057 *non European Officials* with the same average number resident it is noted that eleven were invalided and five died during the year.

The total labour force with their dependants on *Estates* is returned as 6,135 but these are exclusive of *Estates* employing entirely Malay or Chinese labour as for such properties data are not reliable. Of the total of 6,135 persons 3,733 were Indians and their dependants and among this group 111 births and 109 deaths were recorded giving birth and death rates 29.7 and 29.2 respectively. There were 33 infant deaths so the infant mortality rate would be 297.2 per 1,000 registered births.

Maternity and Child Welfare Work—There is no special Maternity Hospital in the State but maternity beds are available at the Kota Bharu Hospital where however in spite of every effort services are not so far popular among Malay women. During the year 187 deliveries were recorded at the Hospital and of these 122 were Indian women 59 were Chinese but only 1 was a Malay. Free facilities are provided for ante-natal treatment and delivery of women from *Estates*. Provision was made for the training of four Malay *bidans* but owing to the illiteracy of Malay women difficulty was experienced in obtaining suitable candidates with the result that only one was selected to commence the course of training (see this *Bulletin* 1938 Supp. p. 197*).

An *Infant Welfare Centre* was started in premises acquired in the market area of Kota Bharu, the work being under the charge of a part time Assistant Lady Medical Officer assisted by an Infant Welfare Nurse. This undertaking has made a most successful beginning the clinic is popular and attendances have steadily increased month by month. The Health Nurse after her daily work at the Clinic visits homes in Kota Bharu and in adjacent kampongs from which births have been reported. The record of the year's work shows that 1,343 visits were paid to newly born infants 1,497 visits were paid to women (958 of these to Malay women) and 1,173 to children (of the latter 703 were Malay children).

School Hygiene—During the year 1 English and 42 Malay Vernacular Schools were inspected and 2,998 school-children medically examined. In towns the general sanitary condition of the schools is satisfactory and it is also said that in areas where anti-malarial measures are efficiently carried out spleen rates are low. Among

other findings it is said that minor skin diseases are common and the percentage among children examined was 21.8 dental caries is equally prevalent with 21.2 per cent. of the pupils examined, anaemia was present in 5 per cent., and diseases of the eye in 2.6 per cent. while 48 cases of active yaws were detected and referred for treatment. A list of pupils and their defects is given to the teachers in towns necessary treatments are supplied at Hospitals and Dispensaries and in rural areas by Travelling and Pack Dispensaries during the course of their weekly visits Hygiene is taught in the schools by teachers.

Public Health Sanitation etc—The lack of a satisfactory index of the general health of the State is again referred to (see this *Bulletin* 1938 Supp. p. 197*) For purposes of public health administration the State is divided into five Districts which cover the main centres of population. Anti-malarial work was carried out along lines previously described in the notified areas the zone of control in Kuala Krai was considerably extended. Additional work undertaken during the year included control measures in a Chinese rubber estate near Kuala Krai, the canalizing of the Sungai Krai the construction of earth drains and the replacement of roadside ditches by concrete drains. Frequent larval surveys were undertaken and regular mosquito surveys were continued.

The single bucket system of sewage disposal continues in use (see this *Bulletin* 1935 Supp. p. 160) Considerable extension of the service is necessary for many houses in the towns and kampongs lack sanitary latrines and are still dependent upon primitive methods of disposal of excreta. Every effort is being made to bring about improvement where the erection of new houses and repairs to old ones are approved the construction of sanitary latrine accommodation is made compulsory Kota Bharu is still the only town in the State having piped water supplies but even here shallow wells inadequately protected are largely used. In all premises licensed for the sale or manufacture of foods and drinks the use of piped supplies has been made compulsory. In other towns in the State supplies are obtained from wells, streams and rivers having regard to the fact that bowel diseases are almost universal, provision of piped supplies is a sanitary necessity. Matters concerned with housing and town planning continued to engage the attention of the responsible authorities, defects are being remedied and improvements in existing conditions gradually effected. The inspection of premises where foods and drinks are prepared or offered for sale was continued. It is stated that conditions in remote villages are in need of great improvement.

On Estates subject to medical inspection the housing of labourers, medical aid and all other matters concerned with the physical welfare of employees received considered attention.

No provision exists for the training of sanitary personnel but it is noted that all the Sanitary Inspectors employed hold the Certificate of the Royal Sanitary Institute, London.

Port Health Work—Coasting steamers plying between Singapore and Bangkok call at Tumpat where the Chief Hospital Assistant at the Tumpat Dispensary acts as Deputy Health Officer and inspects all passengers during the year 175 steamers with 433 passengers called at the port but no case of infectious disease was recorded.

Hospitals Dispensaries etc—Hospitals maintained by the Medical Department remain as previously described except that it is necessary to add that certain extensions to existing buildings were completed during the year (see this *Bulletin* 1937 Supp p 192* and 1938 Supp p 193*). In addition to the Out patient Departments established at all Hospitals there are *Dispensaries* at five centres 2 *Motor Travelling Dispensaries* 2 *Outboard Motor Prahu Dispensaries* and 2 *Pack Dispensaries*. The volume of work dealt with by Hospitals and Dispensaries during the year may be set out as follows —

Institution	Admitted	Treated	Deaths	Out patients	Attendances
Hospitals	6 358	6 663	249	40 057	52,292
5 Dispensaries	—	—	—	41 083	66,500
6 Travelling Dispensaries	—	—	—	—	160 469

Information concerning *disease incidence* in the State is available only from the records maintained by Hospitals, Dispensaries and Travelling Dispensaries reference to some of the diseases treated during the year is made in the notes which follow

Malaria is the principal disease and chief cause of death in the State—it is mainly prevalent in the foothills of Ulu Kelantan and is endemic on most of the rubber estates lying along the banks of the Kelantan River. During the year under review there was a marked increase in the number of malaria cases admitted to hospitals attributed in part to the Japanese Iron Mine at Temangan where health conditions remained unsatisfactory with malaria highly prevalent. The advisability of changing the line site on this Mine and erecting lines in clearings remote from jungle is under consideration. Hospital returns show 2 078 patients admitted for malaria and 2 110 treated with 64 deaths and in addition 18 cases of *blackwater fever* admitted from estates and mines were treated with two deaths. Among the total cases treated *subtertian* infections predominated with 1 310 cases of *benign tertian* there were 247 of *quartan* 36 of *malarial cachexia* 187 mixed infections accounted for 13 and in 317 cases the type of infection was not determined

Estate Health Statistics show that among 6 135 persons 1,553 malaria cases were treated with 29 deaths.

At Hospital Laboratories and Dispensaries 8 811 blood films were examined for the presence of malaria parasites but findings are not recorded. Mention has been made in the section *Public Health* above of anti malarial work it remains to add that the species caught during the frequent larval surveys included *A. maculatus* (the chief vector in hilly districts) *A. barbirostris* and *A. hyrcanus* (prevalent in the flat coastal regions) *A. karwari* *A. vagus* and *A. kochi*

No case of *plague* or *cholera* was notified 1 760 anti-cholera inoculations were given to pilgrims to Mecca (see this *Bulletin* 1938 Supp p 199*). Of *smallpox* 8 cases were reported among employees on an estate. Infection was traced to new arrivals from India 13 000 vaccinations were carried out and quarantine measures were applied to the estate. In the State as a whole 26,265 vaccinations

One case of tropical typhus and two of were performed during the year. *dysentery* with one death were reported. Nine cases of *enteric fever* were admitted to Hospitals making with three cases remaining from 1936 a total of 12 cases treated. Four of these patients died. The source of infection was not traced in any of these cases. For *dysentery*, 83 patients were treated in hospitals and 7 died of the total cases 59 were amoebic, and 25 bacillary. *Diarrhoea* and *enteritis* was responsible for 69 in-patient cases and 6 deaths at ages 2 years and over but no cases were recorded at ages under 2 years.

The incidence of *pulmonary tuberculosis* remains high among 180 cases (160 admitted during the year) of all forms of *tuberculosis* 175 were pulmonary and 45 of these patients died. It is said that recorded cases are no true index of the amount of the disease in the State for cases are rarely seen except in the advanced stages. Many of the cases recorded during 1937 were Government servants detected at the routine examination for *pulmonary tuberculosis* each year. Estate Health Statistics show 279 cases of "lung diseases" treated, with 40 deaths. *Pneumonia* another serious cause of disability and mortality was responsible for the admission of 118 patients and 36 deaths during the year.

No reference occurs in the text of the Report to *helminthic infections*. Hospital Returns show that 249 cases were admitted and 259 treated for *ankylostomiasis* and 101 admitted and 103 treated for *ascariasis*. Estate Health Statistics record 64 cases of *ankylostomiasis* dealt with during the year.

Of *leprosy*, the Report observes. The number of lepers in the State is not known, but assuming the incidence rate is in the same proportion as in neighbouring States, the total number must go into thousands" (see this *Buildin* 1933 Supp. p. 199*). A survey of the State for the disease is proposed. There is accommodation in the State for male lepers only near Tampat. During the year 9 lepers were admitted to this small settlement. 19 were treated, 6 absconded and one was discharged. Ten lepers were also accommodated at Pulau Jerejak (Penang) where 2 died, and 2 were accommodated at Sungai Buloh (Selangor). Treatment continued along lines previously described.

Facilities for the treatment of *venereal diseases* remain as described in the previous issue of this Supplement. During the year 2,242 new cases presented themselves for treatment. Among Hospital in-patients there were 101 cases of *syphilis* 57 of *soft chancres* 149 *gonococcal infections* and 54 of *granuloma venereum*. Attendances at all treatment centres for years totalled 26,493 Malay patients accounting for 24,621 of the total attendances.

Among other diseases referred to in the Report under review mention is made of *beriberi*. 25 cases were admitted and 29 treated in Hospitals, but it is said that the true incidence of the disease in the State is not known. For chronic *ulcers* 321 patients were treated, while for wounds by cutting or piercing instruments 720 patients were dealt with.

Scientific.—At Hospital Laboratories 19,730 specimens were examined of these 8,811 were blood films, 4,884 faecal specimens, 4,577 specimens of urine and 477 were specimens of serum submitted for *hahn* tests. The results of these examinations are not supplied. The *Annual Report of the Veterinary Inspector* is presented as an

Appendix to the Report under review. Mention is made of two cases of *rabies* both confirmed by the Institute of Medical Research, Kuala Lumpur. A muzzling order was introduced and instructions issued for the destruction of all unmuzzled dogs.

Financial—Expenditure on Medical Department services in 1937 amounted to £201,945 a sum which represents 7.3 per cent of the total expenditure of the State during the same year.

Trengganu (1937)

The State of Trengganu lies on the eastern seaboard of the Malay Peninsula 4° and 5°5' N lat. and 102°20' and 103°30' E long. It has an area of 5,050 sq. miles.

Vital Statistics—It is considered that registration is now fairly complete with Deputy Registrars established at 42 centres (see this Bulletin 1938 Supp. p. 200*). Any fine analysis of the causes of death would be useless having regard to the fact that less than 3 per cent of the total deaths registered are certified by qualified medical practitioners. The relevant facts for the year under review are as follows—
Estimated mid year population 198,248 registered births 6,845 deaths 4,427 infant deaths 1,202 stillbirths 295. The crude birth and death rates were 34.5 and 22.3 per 1,000 respectively, the infant mortality rate 175.6 per 1,000 live births and the stillbirth rate 43 per 1,000 births.

The average monthly population on *Estates and Mines* during 1937 was 7,202. During the year 84 deaths occurred amongst employees and their dependants.

Europeans resident in the State numbered 27 and of these 20 were European Officials with an average number resident of 14. One invaliding only was recorded but no deaths.

Maternity and Child Welfare Work—There are 5 midwives in the service of the Medical Department and a nurse also qualified as a midwife. Three other qualified midwives are resident in the State one of them employed by the Nippon Mining Company, Dungun. The volume of maternity work dealt with at various centres can conveniently be set down in the following manner—

Centre	Maternity Cases Conducted					Maternal Deaths
	Malays	Chinese	Indians	Others	Total	
Kuala Trengganu Hosp.	13	84	4	1	102	1
Town Clinic (Japanese Midwife)	61	37	1	2	101	0
Berut (Malay Midwife)	50	4	1	0	55	0
Dungun (Indian Midwife)	12	19	0	0	31	0
Kemaman (Chinese Midwife)	3	57	1	1	61	0
Totals	138	201	7	4	350	1

Of the 175 women who made 307 attendances for ante-natal examination at these centres 114 were Malays 52 were Chinese 6 were Indians and 3 were members of other races.

At the Kuala Trengganu Town Clinic 69 patients attended for ante-natal treatment 225 infants under one year of age and 1 117 children between the ages of one and twelve years also attended for treatment. It is hoped to build up gradually *child welfare* services in the districts with the assistance of local midwives. It is interesting to note that infant mortality rates are high in the south and much lower in the north of the State while highly malarious inland districts show lower rates than urban areas. Malaria would not therefore seem to be the major factor in the problem of infant mortality—in inland districts where money is scarce breast feeding is the practice but in the towns sophisticated foods replace the natural method.

School Hygiene.—Twenty three Government Schools and ten Private Schools were inspected during the year and 2,148 children medically examined, which means that 85 per cent. of the children on the registers were dealt with of the total children examined 1,232 were in Kuala Trengganu schools Pupils showing enlarged spleens formed 3 per cent of the total examined spleen rates for coastal towns ranged from 0.8 per cent to 27.4 per cent and for inland areas between 2.8 per cent and 42.9 per cent Signs of yaws were noted in 3.8 per cent of the children examined, mostly tertiary lesions of the hands and feet Dental caries was noted in 50 per cent. of the children A "great number" of the pupils are said to be infected with worms in faecal specimens of 116 pupils in Kuala Trengganu 111 were positive with ova.

Public Health Sanitation etc.—There are now Town Boards at *ten* places (see this *Bulletin* 1938 Supp. p. 202*). During the year the Medical Officer was appointed Health Officer Kuala Trengganu Assistant Health Officers were appointed at Chukai and Dungun, and in smaller places Dressers act as Health Inspectors. It is said that the larger towns are free from malaria and that *anti-malaria measures* are most needed where such are most difficult to implement. Mosquito surveys were carried out by Health Inspectors in various areas. As regards *sewage disposal* a double pit system was inaugurated in Kuala Trengganu superseding the former system and in Kuala Dungun and Chukai the conservancy systems were extended elsewhere conditions remain unchanged (see this *Bulletin* 1937 Supp. p. 196*). Disposal of *refuse* is by controlled tipping in the larger towns and by burning and burying in the villages. The position in respect to *water supplies* remains as previously described (see this *Bulletin* 1937 Supp. p. 196*). In the crowded parts of Kuala Trengganu water sold by bullock cart is obtained from wells potentially dangerous.

Housing and Town Planning matters continue to engage the attention of the Town Boards and progressive improvement is reported.

With regard to *labour conditions* three mines have small hospitals and employ dressers and a fourth has a large hospital and dispensary and employs a qualified Indian sanitary inspector and staff of coolies. Health conditions on estates are said to have been greatly improved. Mines have been reconstructed, piped water supplies installed crèches for children established and anti-malarial works undertaken. All

mines and estates were visited by the Medical Officer or by Assistant Medical Officers and Sanitary Inspectors during the year. Premises licensed for the manufacture and sale of *foods and drinks* are regularly inspected by Health Inspectors.

Port Health Work—The passengers and crews of 241 junks were examined and special precautions taken in view of the continuance of *cholera* in Siam.

Hospitals Dispensaries etc—Additional accommodation was provided by the completion of new buildings during the year. These included new wards to the Kuala Trengganu Hospital the first ward of a new hospital at Kuala Dungun a ward at Chukai Kemaman Hospital where a new hospital is being built. With these additions there are now 213 hospital beds available for in patients. The work performed at all hospitals during the year is detailed hereafter—

Hospital	Beds	Admissions	Treated	Died
Kuala Trengganu, General	158	2,622	—	49
Garol	7	64	—	1
Kuala Dungun	20	453	—	7
Chukai Kemaman	28	275	—	9
Totals	213	3,414	3,538	66

For the treatment of out patients permanent *Dispensaries* are established at 7 centres (these also include Out patient Departments at Hospitals) there are 6 *Travelling Dressers* who deal with cases in outlying villages *vaccinators* who distribute medicines during their visits and 11 *Police Stations* and 4 *Customs Stations* situated in places where there are no dispensaries supplied with stocks of simple drugs. Patients treated during the year were—

	New Cases	Attendances
By Dispensaries and Travelling Dressers	125,740	157,853
Vaccinators	15,822	16,571
Police and Customs Stations	863	863

Hospitals maintained by Mining Companies and Estates have been referred to in the Section *Public Health* above.

The most reliable information as regards the *incidence of disease* in Trengganu is supplied by the statistics of patients treated at Hospitals and Dispensaries and the notes which follow briefly summarize references to some of the prevailing diseases discussed in the Report under review.

The incidence of *malaria* varies widely in different parts of the State these variations being indicated by the spleen rates recorded at the medical examinations of school-children (see *School Hygiene* above). During the year under review there were 579 admissions to Hospitals for the disease (representing 17 per cent of the total admissions) and 587 patients were treated for malaria with 8 deaths. For the total cases treated types of infection were distributed as to 188 *subtertian* 113 *benign tertian* 24 *quartan* 12 were mixed infections 13 malarial *cachexia* and 237 were unclassified. Out patients treated at Hospitals and Dispensaries totalled 20,860. No case of *blackwater fever* was recorded.

Mining Companies with an average monthly population of labourers and their dependants of 5,042, reported 1,247 cases of malaria and 8 deaths. Estates with an average monthly population of labourers and dependants of 2,160 supply no record of malaria cases but report 7 deaths due to this cause.

It is of interest to note that in the State as a whole only 84 deaths were medically certified as being due to malaria while 2,677 deaths were ascribed to unspecified fevers. 19 of the latter were stated to be due to *demon hepialm* which means a long continuous fever and might be enteric or typhus, but no cause can be assigned to the remainder (see also this Bulletin 1938 Supp. p. 203*).

At the Laboratory where 4,180 blood films were examined, 3,603 gave negative findings. The positives included 290 *P. falciparum*, 228 [? 221] *P. vivax*, 33 *P. malariae* and 33 mixed infections.

No case of *plague cholera smallpox* or other dangerous infectious disease was reported during the year. 12,394 anti-smallpox vaccinations were performed and of these 11,742 were primary vaccinations.

Three non-fatal cases of *tropical typhus* were treated at Hospitals. All diagnoses were confirmed by serological tests and typed as to 2 Scrub type (*Proteus* X K strain) and one Shop" type (*Proteus* X V strain).

Only 9 (non-fatal) cases of *enteric fever* were reported. At the Laboratory where 26 Widal reactions were performed, in 5 cases the serum agglutinated positively with *Bact. typhosum* and 1 with *Bact. paratyphosum B*. Sixty-two in-patient and 186 out-patient cases of *dysentery* were dealt with. 19 of the in-patient cases and 24 of the out-patient cases were amoebic dysentery. Six Hospital deaths were ascribed to the disease. On *Mines and Estates* 38 cases of dysentery were recorded. Among 4,230 faecal specimens examined at the laboratory 13 were found to contain the protozoan *E. histolytica* alone or with other infections.

Fifty-one deaths in the State are said to have been due to *tuberculosis*. It is noted there were 78 in-patient cases of tuberculosis (all forms) and of these 74 patients were suffering from the *pulmonary* form of the disease, and 17 died (i.e. 23 per cent. of total hospital deaths). The majority of the patients were Chinese. At the laboratory where 492 specimens of sputum were examined 70 were positive with *Mycob. tuberculosis*.

Beriberi was less prevalent during the year under review. Deaths due to this cause in the State as a whole numbered 23. Cases treated by the Medical Department totalled 1,180 and of these 117 were in-patients of whom 2 died. On Mining properties 291 non-fatal cases were reported. Incidence is said to be greatest among the Chinese, in women it is usually noted after a confinement. It is rare in the interior where home-grown rice is the staple diet but common on the coast. The low mortality is partly attributed to the fact that all cases were treated with concentrated injections of Vitamin B₁.

Helminthic infections are very prevalent. 72 per cent. of the 4,230 faecal specimens examined at the laboratory had some kind of helminthic infestation which was usually multiple with *ancylostoma* present in 27.4 per cent., *ascaris* 52.3 per cent. and *trichuris* 45.2 per cent. Hospital Returns show 111 in-patient cases of *ancylostomiasis* and 143 of *ascariasis*.

Leprosy—During the past five years a register has been kept of all lepers coming to the notice of the Medical Department. Of the 90 persons recorded over the period 28 have died 10 have left the State 6 are at the Leper Settlement Sungai Buloh (Selangor, F.M.S.) 16 cannot be traced and 30 are known to be alive.

Veneral Diseases—It is said that *syphilis* is rarely seen among local Malays and that the majority of the cases are Chinese. Admissions to hospitals with distinction as to race were as follows—

	Malays	Chinese	Indians	Others	Totals
Gonorrhoea	103	54	44	0	201
Syphilis	3	22	7	1	33
Soft Sore and Granuloma venereum	9	11	9	0	29

In addition to the above 1 018 persons received out patient treatment for gonorrhoea. The figures are said to be no measure of the incidence of the disease which is believed to be very common in the towns.

Cases of *warts* treated during the year were *in patients* 231 and *out-patients* 3 694 (see also *School Hygiene* above).

Laboratory Returns show that out of 244 Kahn tests 50 were positive and that 204 out of 368 specimens were positive with *N. gonorrhoeae*.

Other diseases dealt with by the Medical Department included 4 797 cases of *influenza* few cases of *mumps* *chickenpox* *measles* and *whooping-cough* 377 in patient cases of *ulcers* and upwards of 200 of *wounds* and *fractures*. Menaces to life other than those contributed by disease are evidenced by the mention of 8 persons killed by tigers 1 by an elephant and 1 by a snake.

Scientific—The Kuala Trengganu Hospital is equipped with a laboratory and all permanent dispensaries are supplied with microscopes for the confirmation of clinical diagnoses. Specimens examined and findings recorded are summarized in an Appendix to the Report under review and have been referred to in the preceding notes.

Financial—Total expenditure on Medical Department services during 1937 amounted to \$112,516 a sum which represents 4.2 per cent of the total revenue of the State (or 4.3 per cent of the total State expenditure) during the same year.

BRUNEI (1937)

The native State of Brunei lies on the north-west coast of the island of Borneo between North Borneo and Sarawak. It is 770 miles from Singapore and has an area of about 2,230 sq miles or rather smaller than the county of Devon. In Brunei Bay lies the Island of Labuan.

ital Statistics—The estimated population for the year under review is given as 35 963. The native population comprises mainly Malays and Bornean races the only alien race of numerical importance being the Chinese. [According to the 1931 census 89.5 per cent. of the population were Malays and Borneans and 8.9 per cent. were Chinese.]

Regular anti-malarial work is possible only at Brunei and Kuala Belait and both of these centres are said to be kept free from malaria. The disease is common in rice-growing areas but little met with on the rubber estates (see this *Bulletin* 1938 Supp. p. 207*) the relative immunity on the latter properties being ascribed to the absence of *A. maculatus*. The Report under review supplies classified lists of collection of anopheline larvae mosquitoes, breeding places etc.

At the Laboratory where 1,239 blood films were examined 146 were positive with malaria parasites and among the latter 70 were sub-*tertian*, 38 *t. nig. tertian*, 34 *quartan* and 4 mixed infections.

The poor diet of the average native—mainly rice and fish—and its relation to the high infant mortality in the State has been mentioned in the section *Maternity and Child Welfare* above. Plentiful supplies of cheap vegetables and native rice would contribute to bring about improvement, but unfortunately few of the people are interested in agriculture and methods of cultivation are primitive. The recent appointment of a European Agricultural Officer may serve to remedy existing conditions. Hospital Returns show that 24 cases of beriberi, one of infantile beriberi, 3 of *aristolosis*, 3 of *malnutrition* and one of rickets were dealt with.

Although only one fatal case of *diphtheria* was notified (from Kuala Belait) it was noteworthy as being the first case of the disease ever reported in the State. Examination of close contacts failed to reveal any carrier.

Two cases of *typhoid* and 5 of *paratyphoid fever C* were treated as in-patients with one death. Seven cases of *disentery* were recorded with 2 deaths. 4 of the cases were amoebic and 3 bacillary infections. Twenty-nine deaths were ascribed to *diarrhoea and enteritis* in the State as a whole.

As regards *helminthic infections* it is said that *ascariasis* is exceedingly common, but that *hookworm* infection is much rarer. All school-children are examined annually for intestinal ova and mass treatment is given as a rule for *Ascari* (see also *School Hygiene* above). Among 1,606 cases of *ascariasis* recorded, 26 were treated as in-patients, while out of 59 persons treated for *ankylostomiasis* 32 were in-patients. At the Laboratory where 2,449 faecal specimens were examined 1,502 gave positive findings. Among the positives 771 contained *Ascari*, 144 *Ancylostoma*, 234 both *Ascari* and *Ancylostoma* ova, 145 *Trichuris* and 7 *E. histolytica*.

Nineteen cases of *pulmonary tuberculosis* were treated in Government Hospitals with 3 deaths but in the State as a whole 18 deaths were ascribed to this cause. Out-patient cases treated for *pulmonary tuberculosis* numbered 29 and for other *respiratory diseases* 1,365. *Bronchitis* caused the death of 2 persons, *pneumonia* 9 and other *respiratory diseases*, 8 during the year.

Genital Diseases.—It is said that while *syphilis* is rare, *gonorrhoea* of a mild type is exceedingly common. Prostatic smears of 50 consecutive male admissions to the Brunei Hospital were taken 18 gave positive findings yet only one of the 18 had visited the Hospital for treatment of *gonorrhoea*. Fourteen in-patient and 32 out-patient cases of *gonorrhoea* are recorded, and 2 in-patient and 109 out-patient cases of *gyna*.

Among *other diseases* it is noted that 3 new cases of *leprosy* were discovered in Kuala Belait—two Chinese and one Indian—all contacts were examined and smears taken with negative results. Among *out patients* 2,561 were treated for *gastro-intestinal ailments* 6,911 for *diseases of the skin* 1,953 for all forms of *violence* 42 for *chickenpox* and one for *tropical typhus*.

Scientific—According to the Laboratory Returns 6,856 specimens of various kinds were examined and reported upon. These included 1,329 blood films, 2,449 faecal specimens, 2,362 specimens of urine and 219 of sputum.

Financial—Total expenditure on Medical Department services during 1937 amounted to \$47,888 a sum which represents 7.3 per cent of the total State expenditure during the same year.

THE STATE OF NORTH BORNEO (1937)

The State of North Borneo occupies with adjacent islands the Northern portion of the Island of Borneo. It lies about 100 miles N.W.N. from Singapore and approximately 120 miles S. of Hong Kong, has a total area of about 31,000 sq. miles, and a coast line of some 900 miles. The territory is under the jurisdiction of the British North Borneo (Chartered) Company; the appointment of the Governor is subject to the approval of the Secretary of State. Headquarters of administration are at Sandakan on the East Coast.

Introductory.—A summary of the Annual Report of the Principal Medical Officer, Dr Percival A. DINGLE, North Borneo appeared for the first time in these pages a year ago (see this *Bulletin* 1938, Supp. pp. 209-13*) when a more comprehensive account than usual was presented describing the scope, responsibilities and activities of the Medical Department concerned. The notes which follow will supply no more than a brief *précis* of the contents of the Report for 1937.

Vital Statistics.—The estimated population at the end of the year was 299,311. The excess of immigration over emigration was 8,469 as compared with the corresponding figure of 3,889 in the preceding year. [Possibly Chinese immigrants owing to the hostilities in China?] Registered births numbered 8,022 and deaths 7,558 giving birth and death rates of 26.8 and 25.2 per 1,000 respectively. Births and deaths are tabulated by sex in five racial groups, but in the absence of similar tabulation of the population it is not possible to compare the specific birth and death rates. Births and deaths are further classified by race and sex for each of 28 Districts and deaths also by Districts in eight age-groups.

Infant deaths numbered 1,298 giving an Infant Mortality Rate of 163.3 per 1,000 live births. These data are also classified with racial distinction—the principal specific rates read Malays 214, Natives of the State 167 and Chinese 151 per 1,000 live births. The principal causes of infant mortality were *diseases of the respiratory system*, *malaria and unspecified fevers* and *diseases of the digestive system*.

The labour force employed on the various *Rubber and Tobacco Estates and Logging Camps* increased from 13,307 on the 1st of January to 18,480 on the 31st of December with an average for the year of 17,189 among these workers 309 deaths were recorded.

Maternity and Child Welfare Work—One certified midwife in Government service is attached to the staff of the Civil Hospital, Sandakan. Two village midwives completed their training at the end of 1936 and were posted to Jesselton and Beaufort respectively for work in neighbouring villages. Two pupil midwives commenced their training in Sandakan in January 1937 and in December were successful in obtaining the certificate granted under the Midwives Ordinance. They were posted to the West Coast for work among native women in the Papar and Membakut districts. Six certified midwives were in private practice in Sandakan.

School Hygiene—In July 60 boys attending the Sandakan Vernacular School were weighed and height and chest measurements taken. To 30 of these boys—all natives of Borneo and of a class who use milk and milk products either very sparingly or not at all in their ordinary diet—a free ration of seven ounces of milk was given daily. The experiment was continued for a month when the average increase in weight of the boys supplied with milk was 2.2 lbs. as compared with an average increase of 0.3 lb. among the controls receiving no milk. During the course of five tours through the Interior and Beaufort Districts, Dr J. C. T. TREGARTHEW examined a large number of natives and among other details records the average splenic enlargements below the costal margin for infants and for children under 16 years of age.

Public Health Sanitation &c.—Anti-malarial measures continued to be carried out along the lines previously described and were extended to include Tawau where the larvae of *A. ludlowi*, *A. umbrosus* and *A. barbipes* were found in swampy land near the township. No mention is made of methods of sewage and refuse disposal, water supplies, etc. and for information on these matters the reader is referred to this Bulletin 1936, Supp. p. 210.

Port Health Work—At Sandakan the principal port of the State 46 vessels entered and 14,918 passengers and crews were examined by the Port Health Officer. The only other port mentioned (see this Bulletin 1936, Supp. p. 211*) is Tawau where 2 vessels entered and 584 passengers and crews were examined.

Hong Kong was declared an infected port on account of cholera between August and November. Deck passengers arriving from Hong Kong were placed under observation at the Quarantine Station (see this Bulletin 1936 Supp. p. 211) and cabin passengers were allowed to land under surveillance. No case of the disease occurred and no infected vessel was reported during the year. In the port of Sandakan 1,576 rats were caught and destroyed. None of the 612 rats examined at the Laboratory was plague-infected.

Hospitals Dispensaries etc.—To the list of Government Medical Institutions described in these pages a year ago (see this Bulletin 1936, Supp. p. 211*) must be added the Sick Rest House established at Sipitang. The records of work dealt with during 1937 at all treatment centres reads as follows:—

Item	5 Civil Hospitals	8 Sick Rest Houses	Other Institutions	Total
In-patients admitted	3 819	1 099	632	5,550
treated	3 944	1 134	817	5 895
Deaths	273	40	31	344
Out patients, new cases	30 400	?	6 100	36 500
treatments	69 784	?	24 372	84 156

Forty nine *Europeans* were admitted and treated in the Civil Hospitals at Sandakan and Jesselton no deaths were recorded.

At the 12 *Government Dispensaries* and 3 *Travelling Dispensaries* new cases treated totalled 146,301 and 3,825 respectively while total treatments carried out at these centres totalled 282,256

Treatment clinics continue to be held at weekly and quarterly intervals at a large number of centres in different parts of the country Dr J. C. T. TREGARTHEN District Surgeon Beaufort and Interior undertook five extended tours during the year visiting Government Dispensaries arranging clinics for the treatment of large numbers of natives at convenient centres along his routes of travel

Two examinations for *Hospital Dressers* for promotion were held during the year For the June examination five Government and three Dressers in private employ sat and seven qualified for promotion in grade Two Government and 4 Dressers in private employ sat for the December examination and 3 qualified for promotion in grade.

The notes which follow briefly summarize the comments of Dr Percival A. DINGLE upon the principal items of 1937 morbidity experience

Of the 1 125 patients admitted to Government Hospitals for *malaria* during the year 497 were admitted to institutions in Sandakan and 14 died 216 to institutions in Jesselton where 7 died and 412 to Sick Rest Houses where 9 deaths were recorded it will be seen that malaria was responsible for 20 per cent of the total cases admitted to all Government Hospitals and approximately 9 per cent of the Hospital deaths due to all causes.

Arrangements have been made at Government Hospitals and Dispensaries for the sale of efficient mosquito nets at cost price 38 nets were sold under this arrangement Treatments for malaria at Government Dispensaries are not quoted but among the findings recorded by Dr Tregarthen (see above) appear the following —

- 8 626 natives examined between Keningau and Bundu Tuhan 93.3 per cent showed enlarged spleens.
- 2 751 Muruts examined *en route* to Pensiangan, 97.2 per cent showed enlarged spleens.
- 822 natives examined in the Tenom district showed spleen index of 86.4 per cent
- 1 010 Muruts examined in the Bokaan country showed splenic index of 92.4 per cent.
- 1 417 natives examined in the Beaufort district spleen enlargement in 91.7 per cent. of cases.

Thirteen cases of *blackwater fever* with 3 deaths were reported the local distribution being Jesselton 4 non fatal Tawau 2 non-fatal Sandakan one fatal Kudat 6 cases two deaths.

Estates—During the year 3 831 estate labourers were admitted to Hospital suffering from malaria and 103 deaths were ascribed to this cause. [It is presumed these patients were admitted to *Estate Hospitals* see above for admissions to Government Hospitals.]

Blood films examined at the 5 Civil Hospitals and at 5 Dispensaries totalled 3 420 and of these 836 or 24·4 per cent were found to contain malaria parasites. Among the positives *P. falciparum* infections were responsible for 28·6 per cent *P. vivax* for 56·3 per cent *P. malariae* for 10·8 per cent and mixed infections 6·3 per cent.

Beriberi was responsible for the admission of 185 cases (16 of which terminated fatally) to Government Hospitals, the local distribution of cases and deaths being Tawau 71 cases 6 deaths Sandakan 64 cases 4 deaths Beaufort 27 cases 2 deaths Jesselton 14 cases 1 death Tenom 6 cases 1 death, and Kudat 3 cases, 2 deaths. It is also stated that 224 estate labourers were admitted to hospitals [non-Government ?] suffering from beriberi and that 7 died.

No case of smallpox appears in the Returns but it is noted that during the year 14 833 vaccinations were performed.

Admissions to Government Hospitals for dysentery totalled 466 and 22 hospital deaths were ascribed to this cause. The principal centres concerned appear to have been Sandakan with 93 cases and 8 deaths Keiungau 97 cases with 8 deaths, and Jesselton 96 cases with 4 deaths. It is also stated that an outbreak of amoebic dysentery occurred in villages in the Kotabeland district 171 cases were reported to have been treated with 34 deaths minor outbreaks also occurred in two other areas. Estate labourers admitted to hospitals [non-Government ?] suffering from dysentery numbered 216 and 20 of these died.

Ninety five cases of pulmonary tuberculosis were admitted to Government Hospitals and 23 hospital deaths were due to this cause. Laboratory examination of 611 specimens of sputum showed 105 positive with *Mycobacterium tuberculosis*. Pneumonia was responsible for 170 cases and 84 deaths while in addition 202 estate labourers received in patient treatment for pneumonia and 72 died.

Helminthiasis—The campaign against *ankylostomiasis* continues along the lines previously described (see this Bulletin 1933, Supp. p. 212*). In Sandakan and Jesselton among the 8,988 persons examined the infection rate was 8·4 per cent. A total of 10,551 treatments among the inhabitants of Sandakan Jesselton and ten other centres of population is recorded during the course of the tours of Dr Tregarthen mass treatment was administered to 11 078 natives, and in other areas treatments were given by the staffs of Government Hospitals and Dispensaries. It is further stated that the mass treatment of labourers was carried out on many estates and 6 621 labourers treated. The Laboratory Report supplies details of the numbers of faecal specimens examined at various centres and findings recorded. Out of 5,593 specimens examined 2,872, or 49·8 per cent contained intestinal parasites of one kind or another. Among the positive findings were *Ancylostoma* ova 14·6 per cent *Ancylostoma* and other helminths 15·1 per cent *Ascaris* alone 32·8 per cent., *Ascaris* and other helminths 7·0 per cent *Trichuris* 6·3 per cent. and *E. histolytica* 20·4 per cent.

To the *Leprosy Settlement* 9 patients were admitted during the year—6 Chinese and 3 Natives of the State. Four patients absconded and

5 died and at the end of the year there remained 69 lepers under treatment distributed as to 47 Chinese 20 Natives of the State and 2 Javanese Treatment continues along the lines previously described (see this *Bulletin* 1938 Supp p 213*) At the Laboratory where 50 nasal and nodular smears were examined 18 were positive with *Mycobacterium leprae*

Veneral Diseases—The V D Clinic at Sandakan continued to function successfully throughout the year with an increase in the numbers of new cases applying for treatment The latter numbered 92 and of these 85 were Chinese 2 were Natives of the State and the remaining 5 were members of other races 352 attendances for treatment were recorded Laboratory examinations of 155 urethral and 168 vaginal smears showed that 118 of the former and 65 of the latter were positive with *N. gonorrhoeae*

As regards *yaws* it is recorded that 6 384 cases were treated during the year these included 6 083 new cases seen during 1937

Scientific—The Laboratory Report contains details of the specimens examined and findings recorded at the five Hospitals and five Dispensary Laboratories The principal items have already been the subject of brief reference in the preceding notes under such headings as *malaria tuberculosis helminthiasis leprosy* and *veneral diseases* The *Report on the Native Health* with special reference to the Sociological and Economic Factors bearing on the Depopulation of the Interior and West Coast North Borneo by Dr J O SHIRCORE (see this *Bulletin* 1938 Supp p 213*) was submitted to Government in December 1936 and published by the Government Printing Office in July 1937

Financial—Total expenditure on Medical Department services during 1937 amounted to \$18,960 (sterling value of the dollar 2s 4d)

HONG KONG (1937)

Hong Kong is one of a number of islands off the south-east coast of China, at the mouth of the Canton River about 91 miles south of Canton and 40 east of Macao Hong Kong is 11 miles long and from 2 to 5 miles wide and has an area of about 32 sq miles It is separated from the mainland of China by the Lyeemoon Pass The peninsula of Kowloon on the mainland, area 2½ sq miles, forms part of the Colony together with the adjacent New Territory The whole Colony has an area of about 345 sq miles.

Introductory—In previous Summaries attention has been drawn to the fact that so often the text of the Report has remained unchanged year after year (see this *Bulletin* 1936 Supp p 197* 1937 Supp p 203* and 1938, Supp p 214*) It is pleasing to note that the Report for 1937 conspicuously avoids the repetitive methods characterizing its predecessors and strikes an original note by introducing appropriate and informative discussion of the outstanding features of public health experience and discriminating commentaries upon the components of public health organization in the Colony for the year under review It is of no little significance to note that instead of requiring a considerable extension of printed matter for the presentation of these welcome features space has been economized with such notable

Estates—During the year 3 631 estate labourers were admitted to Hospital suffering from malaria and 103 deaths were ascribed to this cause. [It is presumed these patients were admitted to *Estate Hospitals* see above for admissions to Government Hospitals.]

Blood films examined at the 5 Civil Hospitals and at 5 Dispensaries totalled 3 420 and of these 836 or 24·4 per cent. were found to contain malarial parasites. Among the positives *P. falciparum* infections were responsible for 28·6 per cent. *P. vivax* for 56·3 per cent. *P. malariae* for 10·8 per cent. and mixed infections 6·3 per cent.

Beriberi was responsible for the admission of 185 cases (16 of which terminated fatally) to Government Hospitals, the local distribution of cases and deaths being, Tawau 71 cases 6 deaths, Sandakan 64 cases, 4 deaths Beaufort 27 cases 2 deaths Jesselton 14 cases 1 death Tenom 6 cases, 1 death and Kudat 3 cases 2 deaths. It is also stated that 224 estate labourers were admitted to hospitals [non-Government?] suffering from beriberi and that 7 died.

No case of smallpox appears in the Returns but it is noted that during the year 14 833 vaccinations were performed.

Admissions to Government Hospitals for dysentery totalled 498 and 22 hospital deaths were ascribed to this cause. The principal centres concerned appear to have been Sandakan with 89 cases and 6 deaths, Keningau 97 cases with 9 deaths, and Jesselton 96 cases with 4 deaths. It is also stated that an outbreak of amoebic dysentery occurred in villages in the Kotabelod district 171 cases were reported to have been treated with 34 deaths. minor outbreaks also occurred in two other areas. Estate labourers admitted to hospitals [non-Government?] suffering from dysentery numbered 216 and 20 of these died.

Ninety-five cases of pulmonary tuberculosis were admitted to Government Hospitals and 23 hospital deaths were due to this cause. Laboratory examination of 611 specimens of sputum showed 105 positive with *Mycobacterium tuberculosis*. Pneumonia was responsible for 170 cases and 84 deaths while in addition 202 estate labourers received in-patient treatment for pneumonia and 72 died.

Helminthiasis—The campaign against *ankylostomiasis* continues along the lines previously described (see this Bulletin 1938 Supp. p. 212*). In Sandakan and Jesselton among the 6 998 persons examined the infection rate was 6·4 per cent. A total of 10 551 treatments among the inhabitants of Sandakan, Jesselton, and ten other centres of population is recorded during the course of the tours of Dr Tregarthen, mass treatment was administered to 11 078 natives and in other areas treatments were given by the staffs of Government Hospitals and Dispensaries. It is further stated that the mass treatment of labourers was carried out on many estates and 8 621 labourers treated. The Laboratory Report supplies details of the numbers of faecal specimens examined at various centres and findings recorded. Out of 5 583 specimens examined 2 872, or 48·6 per cent., contained intestinal parasites of one kind or another. Among the positive findings were *Ancylostoma* ova 14·6 per cent. *Ancylostoma* and other helminths 15·1 per cent. *Ascaris* alone 32·8 per cent. *Ascaris* and other helminths 7·0 per cent. *Trichuris* 6·3 per cent. and *E. histolytica* 20·4 per cent.

To the *Labour Settlement* 8 patients were admitted during the year—6 Chinese and 3 Natives of the State. Four patients absconded and

5 died and at the end of the year there remained 69 lepers under treatment distributed as to 47 Chinese 20 Natives of the State and 2 Javanese. Treatment continues along the lines previously described (see this *Bulletin* 1938 Supp p 213*) At the Laboratory where 50 nasal and nodular smears were examined 18 were positive with *Myco leprae*.

Veneral Diseases—The V D Clinic at Sandakan continued to function successfully throughout the year with an increase in the numbers of new cases applying for treatment. The latter numbered 92 and of these 85 were Chinese 2 were Natives of the State and the remaining 5 were members of other races. 352 attendances for treatment were recorded. Laboratory examinations of 155 urethral and 168 vaginal smears showed that 118 of the former and 65 of the latter were positive with *A. gonorrhoeae*.

As regards *yaws* it is recorded that 6,384 cases were treated during the year these included 6,083 new cases seen during 1937.

Scientific—The Laboratory Report contains details of the specimens examined and findings recorded at the five Hospitals and five Dispensary Laboratories. The principal items have already been the subject of brief reference in the preceding notes under such headings as *malaria tuberculosis helminthiasis leprosy and venereal diseases*. The *Report on the Native Health* with special reference to the Sociological and Economic Factors bearing on the Depopulation of the Interior and West Coast North Borneo by Dr J O SNIRCORE (see this *Bulletin* 1938 Supp p 213*) was submitted to Government in December 1936 and published by the Government Printing Office in July 1937.

Financial—Total expenditure on Medical Department services during 1937 amounted to \$18,960 (sterling value of the dollar 2s. 4d.)

HONG KONG (1937)

Hong Kong is one of a number of islands off the south-east coast of China, at the mouth of the Canton River about 91 miles south of Canton and 40 east of Macao. Hong Kong is 11 miles long and from 2 to 5 miles wide and has an area of about 32 sq miles. It is separated from the mainland of China by the Lyeemoon Pass. The peninsula of Kowloon on the mainland, area 2½ sq miles, forms part of the Colony together with the adjacent New Territory. The whole Colony has an area of about 34½ sq miles.

Introductory—In previous Summaries attention has been drawn to the fact that so often the text of the Report has remained unchanged year after year (see this *Bulletin* 1936, Supp p 197* 1937 Supp. p 203* and 1938 Supp p 214*) It is pleasing to note that the Report for 1937 conspicuously avoids the repetitive methods characterizing its predecessors and strikes an original note by introducing appropriate and informative discussion of the outstanding features of public health experience and discriminating commentaries upon the components of public health organization in the Colony for the year under review. It is of no little significance to note that instead of requiring a considerable extension of printed matter for the presentation of these welcome features, space has been economized with such notable

success that without sacrificing any feature meriting inclusion, by comparison with its immediate predecessor the 1937 Report is a ~~smaller~~ volume by 60 pages, thus representing a saving of about 25 per cent.

Vital Statistics—This section has undergone complete revision. The difficulties attending attempts to make an annual estimate of the Chinese population—difficulties enormously increased for the year under review when a serious refugee problem developed as the result of the Sino-Japanese disturbances—are discussed, together with a brief description of the system applied for the registration of births and deaths. As an example of the importance of the part played by local customs or practices in influencing the interpretation of assembled facts and of the value of explanatory text in such connexion a brief reference to the birth registration among the Chinese population in Hong Kong is of particular interest. It is explained that partly as a result of ignorance or laziness, and partly owing to the Chinese custom of postponing the event until the child is in its second year birth registration is still incomplete.† On the other hand, since the outbreak of Sino-Japanese hostilities the tendency has developed amongst the Chinese to secure registration of births in Hong Kong as a preliminary step towards claiming British nationality even when the evidence of local birth is of the most slender.

The relevant vital statistical data for 1937 may be summarized as follows—

Estimated Populations

Item	Island of Hong Kong	Kowloon and New Kowloon	New Territories	Mantau	Totals for the Colony
Non-Chinese	9,847	10,887	478	1,372	22,584
Chinese	457,982	339,360	107,052	100,000	904,400
Totals	467,829	350,247	107,530	101,372	1,026,978

Births, Deaths, and Infant Deaths.

Item	Births	Birth Rate	Deaths	Death Rate	Infant Deaths	I.M.R.
Non-Chinese	682	30.6	244	10.8	30	45.9
Chinese	31,811	22.1	34,391	24.9	11,620	376.0
Totals	32,493	32.1	34,635	34.4	11,650	369.2

† [But it is to be noted that the Chinese method of reckoning age adds a variable number of months to the true age, one year being added at the time of birth and another on the first subsequent Chinese New Year's day so that a child born say in January 1937 is said to be one year old at birth and two years old on the Chinese New Year's day in February 1937 and one born say in March 1937 remains one year old up to New Year's day in February 1938 when it becomes two years old by Chinese reckoning. A formula and tables for converting Chinese ages to their European equivalents are given by STEVENSON and PAN MING TSIU in the Chinese Medical Journal 1929, Vol. 41, pp. 122-130 (1937).]

The registered births include 744 post registrations after 12 months viz 705 Chinese and 39 Non-Chinese these have been deducted when calculating the infant mortality rates. As regards registered deaths the monthly average for the first seven months was 2,349 and for the last five months 3 638. The refugee problem and the typhoon were largely responsible for the increase (see also hereafter under *Public Health*)

European Officials resident in the Colony numbered 940 with an average number resident of 918. Seven were invalided and three died.

In an Appendix to the Report under review the Registrar-General supplies the demographic facts for 1937 in considerable detail.

Maternity and Child Welfare Work—In Hospitals under Government and voluntary control 358 beds were available for maternity cases in 1937 while additional accommodation was also available in a large number of maternity homes of the latter 75 were inspected during the year. At Government Hospitals 4,230 women appear to have been treated for diseases of pregnancy and the puerperal state (with 14 deaths) 3 679 being cases of normal labour. At Chinese Hospitals among 6 439 cases (38 deaths) 6 079 were cases of normal labour. Large numbers of ante-natal and other cases are seen in the out patient departments of the Maternity blocks of the various hospitals and at Government and Chinese Dispensaries.

As from the 1st January 1937 the practice of midwifery habitually and for gain (by unregistered persons) became a punishable offence. "Wan P'os" or handy women who had practised midwifery in Hong Kong for two or more years previously and who enrolled as midwives were exempted from this prohibition. 111 Wan P'os took advantage of the concession and were enrolled. At the examinations of the Midwives Board 37 candidates were successful at the end of the year the names of 395 women were on the Midwives Register. The 16 midwives employed by the Medical Department provide free services at the homes of poor women and children and when not engaged in maternity and child welfare work assist in first aid work at the dispensaries.

Ante natal and infant welfare work continues to be carried out at a large number of centres. Personal hygiene and mothercraft are taught to the women attending these centres.

School Hygiene—The School Hygiene Branch (comprising one European and two Chinese Health Officers a part time Lady Medical Officer and five Nurses) is responsible for the medical supervision of school-children, and the inspection of school premises. With this limited staff responsible for a school population exceeding 86 000 attending over eleven hundred schools it is clear that it is possible to examine only a small proportion of the children. During the year 5 802 medical examinations were carried out in 18 Government schools. [There are 21 Government schools 19 Grant-in Aid schools and 1 137 private schools in the Colony.] Dental defects and visual disorders were the conditions most frequently met with. The establishment of a School Dental Department under the charge of a Government Dental Surgeon is recommended. At the various School Clinics attendances of scholars for examination and treatment totalled 2 780 while in addition 76 visits were paid by School Nurses to the homes of scholars.

At the request of the Education Department a large number of premises being used as schools (presumably as private schools) were inspected and many of them found to lack the elementary amenities demanded for the proper accommodation and instruction of young people. It is hoped to amend existing legislation on the subject of school hygiene to ensure that reasonable standards shall be maintained in all schools, for as the Report rightly observes "It cannot be emphasized too strongly that by far the best method of teaching hygiene to scholars is by ensuring that the school premises themselves are satisfactory from the public health standpoint."

Public Health Sanitation etc—Dr P. S. SELWYX-CLARKE the newly appointed Director of Medical Services, describes the exceptional difficulties with which the public health authorities had to contend, and the unusual factors which combined to influence adversely the health of the community and to give rise to an increased amount of morbidity and mortality during the year under review. The continuance of the Sino-Japanese hostilities and their increasing intensity drove large numbers of refugees to seek a haven in Hong Kong their influx served to aggravate insanitary conditions in the already congested urban area. Refugees from areas in China where health services had become disorganized brought with them the seeds of dangerous infections—dreadful cholera and smallpox epidemics resulted. In September a typhoon of exceptional severity devastated the Colony and while no accurate estimate of the loss of life is possible it may be noted that the bodies of some 490 persons who had been killed or drowned were picked up along the harbour foreshore. Even the most adequately staffed and wisely organized public health service would have found it difficult to maintain essential services and at the same time successfully cope with a series of calamities of this order but in Hong Kong the anomalous arrangements underlying some of the components of public health administration (see this *Bulletin* 1935 Supp. p. 191*) must have served to intensify the problems of efficient control. The whole of the European and Asiatic Sanitary Inspectorate while theoretically grouped round the Health Officers in actual practice are not controlled by Medical Officers of Health but by a layman, the Chairman of the Urban Council of Hong Kong. The present system is unsatisfactory from every point of view—Medical Officers of Health working under these conditions may be likened to Army Officers endeavouring to carry out their complex duties deprived of their C.O.s. A more effectively organized and adequately staffed sanitary inspectorate under the direct control of the Medical Officers of Health would have been able to deal more successfully with such dangerous infections as smallpox and cholera which during 1937 and in recent years have exacted so heavy a toll of life and suffering. Reorganization of the Health Division with the sanitary inspectorate under the direct supervision and control of the Medical Officers of Health is urgently recommended.

Anti-malarial work continued to be carried out under the auspices of the Malaria Bureau with unabated energy in the report of the Malaria Bureau these activities are described in detail.

The objectionable bucket system of *sewage disposal*—which continues to function in the majority of tenements and shop-houses—and local methods applied for the collection and removal of night-soil, are the

subject of description and criticism. The present systems constitute grave sources of danger to the public health and steps are being taken to investigate the possibility of introducing drastic changes which envisage sewer disposal. Methods of *refuse disposal* are discussed and the defects of existing arrangements exposed. The system is capable of improvement and steps are being taken to this end.

The completion of the Shing Mun Jubilee Dam during the year marked a notable stage in the development of public health utilities in the Colony. *Water supplies* are now adequate for the impounding reservoirs (8 on the island and 5 on the mainland) have a combined storage capacity of 5,971 million gallons.

Matters concerned with *housing and town planning* are discussed at some length and various recommendations for future work in this field are outlined. These include new legislation to control town planning etc. and schemes for slum clearance. It may be noted that at present the Sanitary Department (see above) has little or nothing to do with housing other than the removal of obstructions.

During the year special bye laws were drafted restricting the sale of certain *foods and drinks* with a view to minimizing the risks of infection through their use. Draft legislation which sought to make the pasteurization of milk compulsory met with considerable opposition. The proposals will probably become effective in 1938. Much information of value is expected to be made available following the investigations of the *Nutrition Research Committee*.

The curiosities of organization characterizing the Sanitary Department (see above) are seen in another direction. health conditions in markets are under the control of the Colonial Veterinary Surgeons instead of under the Health Officers. Until the reorganization of the Health Division has been carried out and the sanitary inspectorate brought under the supervision and control of Medical Officers of Health, the effective *training of sanitary personnel* cannot be provided for.

Port Health Work—Services continued to function as usual. Due to the Sino-Japanese disturbances a decrease in the number of ships entering the Port is recorded. The principal items of work concerned with shipping during the year may be summarized as follows—

British ocean-going ships entering and clearing	4,322
Foreign	5,202
Other vessels entering and clearing	24,258
Total tonnage dealt with	36 191 724
Emigrants examined	245 488
Emigrants rejected	1 153

Several new *air services* were inaugurated during the year. no cases of infectious disease were discovered in passengers or crews of aircraft. The volume of aerial traffic dealt with during 1937 may be gauged from the following data—

Aircraft	Arrivals	Departures
Crews	398	395
Passengers	1 150	1 133
	1,929	1 756

Hospitals Dispensaries etc—In the words of the Report under review The outstanding event in the year as regards improved hospital facilities was the opening of the Queen Mary Hospital which

replaced the old Government Civil Hospital built in 1874 and which was closed on the 30th of June 1937.

The Queen Mary Hospital, which embodies all the latest improvements in hospital construction and equipment has accommodation for 548 beds, an Isolation Wing consisting of nine small wards accommodates 22 patients. About a quarter of the beds in the new hospital are allotted to the Medical, Surgical, and Gynaecological and Obstetrical clinical units of the Hong Kong University. Private practitioners are privileged to make use of the Maternity Wing for the treatment of their own cases.

The first patients were admitted in May 1937 from the Victoria Hospital, by the end of June all the patients had been transferred to the new hospital from the old Government Civil and Victoria Hospitals.

The returns for Government and Chinese Hospitals are presented in appendices to the Annual Report. For present purposes it must suffice to summarize briefly the record of the year's work by stating that to Government hospitals during 1937 admissions numbered 17,832, cases treated 18,275 and hospital deaths 1,637. Out-patients treated at Government Hospitals exceeded 130,000—these are exclusive of out patients treated at special clinics, dispensaries, etc. At Government Dispensaries alone 59,818 patients were dealt with.

A new and informative account of the origins and subsequent development of the Chinese Hospitals and Public Dispensaries is a feature of the Report under review. Dangerous overcrowding characterizes many of the Chinese hospitals and it is observed, it is not at all uncommon to see two patients, young and old, in the same bed, five adult women in two beds pushed close together, patients lying all over the ward floors so as to render separation of types of disease and medical attention and nursing matters of extreme difficulty. In one case 61 patients were found in a ward of 12 beds! This distressing state of affairs is in urgent need of reform and it is hoped steps may be taken to improve existing conditions in the near future. To the Chinese Hospitals 46,849 patients were admitted, 47,869 were treated and 12,641 died during 1937. The Chinese Public Dispensaries dealt with 264,589 new and 238,527 old cases during the year under review.

Mention has already been made of the fact that owing to exceptional circumstances the public health suffered a set-back during 1937 (see *Public Health* above) and that during the late summer a marked increase in morbidity and mortality experience was noted. As regards the principal diseases responsible for disease and death, the notes which follow briefly summarize the more extensive commentaries provided in the Report under review.

A serious outbreak of cholera occurred. The disease was first recognized in July though it is significantly observed "notifications of dysentery had already shown a marked increase in June." In July 13 cases were reported, in August 1,100 and in September 500 thereafter incidence declined rapidly and only one case was notified in December. Altogether 1,690 persons were affected and 1,082 died. Undoubtedly the epidemic was one of the legacies of the disturbed conditions in China—the infection was probably introduced by refugees from South China. Extensive preventive measures were instituted and energetically applied. Over a quarter of a million inoculations were carried out at hospitals, public dispensaries, and at

centres staffed by the St John Ambulance Association and Brigade. Having regard to the inadequacy and faulty organization of the sanitary staff insanitary methods of night-soil disposal etc. what is surprising is not the sudden development of the epidemic to alarming proportions but the success which followed the application of control and preventive measures in a dangerous situation.

Cases of *smallpox* were notified in Hong Kong during every month of 1937 with the sole exception of October. The largest monthly total was recorded in April though a second and as it proved more serious peak occurred in December. Altogether 129 cases with 94 deaths were notified during the year. Nearly half a million persons were vaccinated and in this connexion it may be noted that 21,232 (or 75 per cent) of the infants registered during the year were vaccinated. The exceptionally high case-mortality rate is suggestive of many missed cases. A more effectively organized sanitary inspectorate would prevent concealment of cases and would lead to the discovery of all contacts.

Though during 1937 *typhus* was rife in many parts of China, no case of the disease was reported in Hong Kong. Sporadic cases of *cerebro-spinal* fever occurred throughout the year with March and April the months of maximum prevalence. Notified cases numbered 157 and 88 of the patients died. No case of *plague* was recorded. The systematic trapping of rats and other anti plague measures continued to be carried out as usual.

Diphtheria was responsible for 308 cases with 148 deaths. maximum incidence occurred in the period November-March. Of the total cases notified 241 were treated in hospitals with 112 deaths. Eight non fatal cases of *scarlet fever* were notified.

Malaria—The anti malarial works carried out under the direction of the Malaria Bureau since its establishment in 1930 have succeeded in making malaria a relatively unimportant disease in urban areas. The infection rate still remains high in some rural areas where anti-malarial activities continue to receive vigilant attention. The Report of the Malaria Bureau describes the year's work in detail. To Government Hospitals 677 cases were admitted and 695 treated with 23 deaths while the corresponding figures for Chinese Hospitals were 1,892 1,931 and 328 respectively. The distribution of types of infection among the 695 cases in Government and the 1,931 cases in Chinese Hospitals reads as follows —

	Benign Tertian	Quartan	Subtertian	Cachexia	Undefined
Government Hospitals	206	8	309	121	51
Chinese ..	286	7	1 053	47	506

At the Government Bacteriological Institute 8,917 blood films were examined for the presence of malarial parasites and in 3,581 cases positive findings were recorded. In the Report of the Bacteriological Institute a graph is interleaved showing the percentage relation of the different types of malarial parasites to each other month by month.

throughout the year and also the rainfall in inches (see also this *Bulletin* 1938 Supp. p. 217*)

July to October were the months of maximum incidence of fevers of the *enterica* group during the year 464 cases with 178 deaths were reported. Government Hospitals dealt with 84 in-patient cases of typhoid and 6 of paratyphoid with 20 deaths and Chinese Hospitals with 211 cases of typhoid with 106 deaths. At the Bacteriological Institute where 1 539 samples of serum were tested for the specific agglutinins of the enteric bacilli, 344 were positive with *Bact. typhosum* 6 *Bact. paratyphosum A* 3 *Bact. paratyphosum B* and 62 type undetermined. The investigation into the presence of agglutinins against typhoid organisms in cases showing no clinical signs of the disease was continued (see this *Bulletin* 1938 Supp., p. 219*)

Preceding the cholera epidemic a significant rise in the reported cases of dysentery was observed (see above *Cholera*). During the year 576 cases were notified (see below) and according to the Report of the Registrar-General 316 deaths were ascribed to the disease. According to the Hospital returns the majority of the cases were bacillary infections, viz. —

	Amoebic	Bacillary	Undefined	Total	Total deaths
Government Hospitals	3	117	4	14	16
Chinese "	165	328	237	728	234

At the Bacteriological Institute where 3 753 faecal specimens were cultured for pathogenic organisms 134 were *Bact. dysenteriae* Flexner 11 Shiga and 17 Schmitz infections.

Tuberculosis was responsible for one in every eleven deaths due to all causes. Cases treated in hospitals may be summarized as follows —

	Government Hospitals		Chinese Hospitals	
	Cases	Deaths	Cases	Deaths
Pulmonary tuberculosis	195	61	3 853	1 898
Other forms	122	48	753	29

Overcrowded living conditions and under-nourishment coupled with the exceedingly common habit among the Chinese of spitting in public places combine to spread the disease. Hospitalization of any but a very small proportion of the infectious patients is at present not possible. At the Bacteriological Institute 174 out of 687 specimens of sputum examined were positive with *Mycob. tuberculosis*.

The number of patients treated in Government and Chinese Hospitals, for various helminthic infections was negligible totalling 317. Among 101 cases in Government Hospitals were 40 cases of ascariasis and 35 of ankylostomiasis while among 216 cases dealt with in Chinese Hospitals, 102 were treated for ascariasis and 44 for ankylostomiasis. Thirty-five patients were treated for clonorchiasis (8 in Government Hospitals). Among 2,407 faecal specimens examined at the

Bacteriological Institute 170 contained ascari 104 clonorchis 42 trichuris 31 ancylostoma and 89 were multiple infections. Little is known of the amount of leprosy in Hong Kong (see this *Bulletin* 1937 Supp p 209*) and until a systematic survey is carried out the situation so far as this disease is concerned must remain conjectural. The question of obtaining the help of the British Empire Leprosy Relief Association to carry out such a survey is under consideration. Out of 154 specimens of nasal and skin smears examined at the Bacteriological Institute 50 were positive with *Mycobacterium leprae*. The facilities for free medical advice and treatment remained as previously described. Details of the year's work at six centres may be summarized as follows —

Centre	New Cases		Attendances	
	M	F	M	F
Queen's Road (Old Govt. Civil Hospital)	1 241	570		
Violet Peel Health Centre	1 345	657	5 838	2 621
South Howloon (Docks)	2 228	481	7 648	2 375
Howloon Hospital	347	834	10 453	2 280
Taiipo Dispensary	28	2	1 752	3 201
Un Long Dispensary	21	5	391	15
			171	23

In patients treated at Government Hospitals for syphilis numbered 127 for soft chancre 112 and for gonococcal infections 207 at Chinese Hospitals the corresponding figures were 234 30 and 62 respectively. At the Bacteriological Institute an interesting comparative study was carried out on the recently described *Ide precipitation test* for syphilis. One thousand sera were tested in parallel with the Kahn test and the following results recorded —

	Kahn test	Ide test
Strong positive	214	243
Positive	133	141
Doubtful	44	51
Negative	609	565
Total	1 000	1 000

Kahn tests were applied to 16,581 samples of blood serum 4 345 gave positive 723 doubtful and 11 513 negative reactions. In addition 617 smears were examined for the presence of the gonococcus but findings do not appear to have been recorded.

Other Diseases — Under this heading mention should be made of the fact that deaths due to diseases of the respiratory system occupied the first place in the list of causes of death and were responsible for 10,380 deaths during the year under review. Beriberi including the infantile variety constitutes a serious problem and no fewer than 1 661 deaths were ascribed to this cause in 1937. In the Table below the cases and deaths recorded in hospitals for certain respiratory affections and for beriberi are summarized.

PACIFIC OCEAN

Fiji and Western Pacific (1937)

The Colony of Fiji comprises some 200 to 250 islands of volcanic origin in the south Pacific Ocean (many merely uninhabited islets and rocks) lying between 15 and 22°S latitude and longitudes 177°W and 175°E. Sydney is about 1700 miles distant and Auckland 1100 miles. The Tongan or Friendly Islands lie 180 miles to the south-east and Samoa 500 miles to the north-east. The principal inhabited islands are Vitilevu with an area of 4 053 sq miles, Vannalevu 2,130 sq miles, Tavunui 217, Kadavu 124, Koro 58, Gau 45, Ovalau 43, Rotumah 14 sq miles. The total area of the Colony is 7 083 sq miles (nearly that of Wales).

Introduction—This Report compiled by Dr V W T McGUSTY, Acting Director of Medical Services, contains a considerable amount of new and interesting information under such headings as *Administration of Public Health Hospitals Medical Education of Native Races* etc relating to the Colony of Fiji. The summary notes which follow do not pretend to deal adequately with the extensive discussions of the above matters which should be considered by the reader *in toto*.

Vital Statistics—The relevant facts may be tabulated as follows—

Race	Estimated Population	Registered Births	Birth Rate	Registered Deaths	Death Rate	Infant Deaths	I.M.R.
Europeans	4,238	71	16.8	36	8.5	1	—
Half-castes	4,756	150	31.5	40	8.4	8	53.3
Fijians	99,595	3,432	34.5	2,128	21.4	331	96.4
Rotumans	2,915	129	44.3	58	19.9	10	77.5
East Indians	89,333	3,357	37.6	801	10.1	187	55.7
Polynesians	1,567	74	47.2	42	26.6	2	27.0
Chinese	1,837	18	9.8	6	3.3	—	—
Others	1,156	53	45.9	14	12.1	4	—
Totals	205,397	7,284	35.5	3,225	15.7	543	74.8

European Officials resident numbered 429 with an average number resident of 336. Five were invalided and two died. Of *Non European Officials* there were 626 resident with an average number resident of 516. One death occurred within this group.

Maternity and Child Welfare Work—The Obstetric Ward of the Colonial Hospital was well patronized as usual. 252 cases were admitted and 219 deliveries recorded. A new Ward is to be built to meet steadily increasing demands. The number of patients attending the *Ante Natal Clinic* steadily increased during the year under review. 85 mothers made 231 attendances for advice and treatment. A *Post Natal Clinic* was started in May and the 16 mothers attending included the wives of the two principal Chiefs.

Native Obstetric Nurses are trained at the Colonial War Memorial Hospital. Government has decided to establish a school with improved facilities for the training of non European women in general and obstetric nursing.

Fijian Infant Welfare work has up to the present been carried out by intelligent native women appointed by the Chiefs of villages to carry out the daily routine services under the supervision of inspecting medical officers assisted by 4 specially trained European Nurses. In 1938 control of this work will pass from the Native Administration to the Medical Department one important result of this change will be that the special staff of infant welfare nurses will be controlled by the Nursing Superintendent.

School Hygiene—All schools throughout the Colony were inspected by District Medical Officers, or Native or Indian Medical Practitioners. Those in the actual Suva urban and rural areas are the special charge of the Medical Officer of Health in these areas a hookworm survey was commenced in August faecal specimens were collected from school-children and examined, treatments being given to the children infested. The following facts are supplied relating to this survey—

Race	Number Examined	Positives	Percentage Infestation
Indians	131	59	45
Fijians	785	285	34
Others	65	6	11

Public Health Sanitation etc—In Fiji Public Health Administration demands the maintenance of two distinct health organizations, in view of the fact that one half of the population consists of communally living natives and the other half of individual groups of immigrants with East Indians predominating. The large majority of native *Fijians* continue to live in tribal units in small scattered villages each under its headman tribal affinities have led to the grouping of villages into larger administrative units and each of these is subject to the authority of a single Chief. These populations are served by Native Medical Practitioners who are posted to the various native areas. On the other hand, the public health staff of the non-native sections of the community comprises one full-time Medical Officer of Health whose direct authority is limited to the port and environs of Suva and medical officers who are *ex-officio* Medical Officers of Health, posted to rural areas, qualified sanitary inspectors, sanitary overseers, and sanitary assistants. All health and curative activities in the Colony are centrally controlled by the Director of Medical Services.

In order to ensure better supervision of the *Sanitary Services* in the town of Suva arrangements were made during the year whereby the Government Medical Officer of Health assumed control of the Town Board Sanitary personnel, and this Officer will in future direct all public health activities in the urban and sanitary areas of Suva. In the Suva rural area a number of new *latrines* were constructed and *septic tanks* installed.

The usual routine sanitary inspections of premises were carried out during the year these are described in detail in the Report under review.

Port Health Work—The Port Health Officer reports that during the year 155 overseas vessels were boarded and 3,323 passengers and 3,802 members of crews medically examined. Vessels arriving from plague

infected or suspected ports from malarial ports vessels not holding deratization or deratization exemption certificates etc. are fumigated by the Port Sanitary Staff 10 overseas and 69 local vessels were dealt with Rat-catching activities were continued 2 604 rats were caught and 600 were bacteriologically examined at the Government Laboratory but all were negative for *P. pestis*

Hospitals, Dispensaries etc.—A very full description is provided of the Hospitals in the Colony It is stated that in Fiji there are no privately owned hospitals [In this connexion there is mention of one hospital owned by the Colonial Sugar Refining Company and one by the Methodist Mission] and with the exception of 13 private Medical Practitioners all medical activities are centred in the Government Curative services extend from the hospitals to the *dispensaries* the latter being under District Medical Officers Native and Indian Medical Practitioners Details of the volume of work dealt with at the various hospitals during 1937 are set out in the following Tables —

Hospital	Admissions	Deaths	Out patients
Colonial War Memorial	2 679	190	18 212
Lautoka	2 601	121	7 129
Lambasa	711	35	9 153
Levuka	323	14	3 467
Provincial Hospitals, etc.	3 717	207	52 553
Central Leper	80	27	—
Mental	45	11	—
Suva Gaol	66	—	300

Native Medical Practitioners in charge of dispensaries treated 44 150 cases and recorded 315 deaths among their patients.

The *Nurses Training School* established in 1934 has served to provide the Colony with trained nurses experienced in local conditions. The expansion of nursing services which is rapidly taking place has led to the decision to replace this School by another in which non Europeans will be trained as nurses to a standard adequate for the purposes of the subordinate nursing posts of the Colony

Medical Education is described in detail in the Report of the Principal of the *Central Medical School* (Dr D W HOODLESS) In addition two unusually interesting articles originally prepared for submission to the Rural Hygiene Conference held in Java in August 1937 have been reprinted with the permission of the Health Section of the League of Nations and are presented in the Annual Report under review The articles are entitled "*The Medical Education of Natives*" by Dr D W HOODLESS and "*The Central Medical School in Suva in Relation to the Health Problems of the Pacific*" by Dr V W T MCGURRY It is impossible in these pages to summarize with adequate justice the contents of these two important articles which deserve the very fullest consideration but attention is especially directed to the concluding observations of Dr MCGURRY's paper which read as follows —

None of the administrations participating in the native medical practitioner scheme could afford to embark on expensive medical services but, by a pooling of resources in the Central Medical School undertaking it is believed they will be able to elaborate a common form of health

organization that will meet the requirements of their native populations. The system is still in an experimental stage in most places but the success that has been obtained in Fiji justifies the hope that the results will prove favourable in other places.

"While the scheme was evolved to meet the special circumstances of communally-living South Sea islanders, experience with the individualistic Indians, although less successful, has also proved it capable of modification to meet other conditions.

Its main essentials are economy and the maintenance of the native medical practitioners as closely as possible at the economic level of the people amongst whom they work, and these considerations are liable to be overlooked by over-enthusiastic supporters, as well as by destructive critics.

(See also this *Bulletin* 1938 Vol 33 pp 828-833)

The following notes briefly refer to the principal items of morbidity experience commented upon in the Annual Report for 1937.

Sporadic cases of clinical *diphtheria* make their appearance from time to time—nine cases were notified but fortunately the degree of virulence was low.

Influenza was very prevalent throughout the Colony and during the year 1784 cases were reported—the disease was mild in type and few cases developed serious complications. Of *measles* 180 cases were reported from country districts.

Dysentery was prevalent during the first quarter of the year and altogether 1,213 cases of bacillary and 24 cases of amoebic dysentery were notified with 67 deaths. The highest incidences recorded were in the Rewa, Nadi, Savu Savu, Suva and Ba districts. At the Laboratory where 734 faecal specimens were examined, 124 were positive with Shiga bacillus 19 Flexner 10 Shultz, 9 Sonne while the protozoon *E. histolytica* was found in 8 cases. Reported cases of *enteric fever* numbered 210.

Tuberculosis is said to be one of the three most widespread communicable diseases endemic in the Colony (the other two being dysentery and enteric fever). During the year 342 cases of the pulmonary and 51 cases of other forms of the disease were notified. A Tuberculosis Survey of the whole population is urgently advised by the Medical Department. Among other compulsorily notifiable diseases recorded during 1937 appear 223 cases of *broncho-pneumonia* and 69 of *lobar pneumonia*.

In the section *School Hygiene* above reference was made to the *hookworm* survey of school-children. The Laboratory Report mentions the examination of 1,948 specimens of stools, and of these 853 were positive with hookworm, 146 Trichuris, 58 Ascaris, and 40 Enterobitis.

Leprosy—The usual comprehensive and useful account of the year's work at the Government Leper Station Makogai, is presented, the 1937 Report being contributed by Dr W. G. MACNAUGHTON who assumed duty as Medical Superintendent when Dr C. J. AUSTIN proceeded on leave at the middle of the year. During the year 60 lepers were admitted, 27 died, 31 were discharged, leaving at the end of the year 577 patients still in residence.

Under the Public Health Ordinance 1935 venereal diseases were made notifiable and treatment compulsory. Syphilis is said to be rarely seen except among the crews of vessels calling at the port of Suva and gonorrhoea appears to be the only venereal disease met with

among the resident population. During the year 340 cases of venereal disease (undifferentiated) were notified. According to the Returns of the Provincial Hospitals 41 cases of syphilis and 109 of gonorrhoea were treated in those institutions during 1937.

Cases of yaws continue to be met with in country districts but the scarring and deformity due to tertiary yaws formerly seen are unknown among the younger generation. Notified cases during the year numbered 4581.

Other diseases calling for brief mention include the following. Twelve cases of *epidemic dropsy* were reported from Ba and two from Suva all occurred among Indians. An Indian woman from the rural district of Suva was admitted to hospital suffering from *undulant fever* the source of infection was traced to the milk of a cow. An Indian case of *cerebrospinal meningitis* was reported and one Fijian case of *cerebral meningitis*. The first case of *Landry's paralysis* to be reported occurred in an Indian adult from Lantoka district. Congenital *skin diseases* particularly *ringworm* and *scabies* are common in Fijian native communities.

Dr S. M. LAMBERT contributes an *Annual Report on the Western Pacific Health Service*. The sanitation campaign was confined to the island of Vita Levu and during the course of the work a large number of homes were surveyed, holes bored, squatting slabs supplied, etc. A tuberculosis and general health survey was carried out in one of the mountain provinces. 3141 persons were tuberculin tested and 1,803 gave positive reactions. Among the whole population surveyed 5 primary, 6 secondary, and 12 cases of tertiary *yaws* were recorded.

Scientific—The work of the Pathological Laboratory is described by Dr D. C. M. MACPIERSON, Government Pathologist. During the year 5731 specimens were examined—the principal of these have been mentioned in the preceding notes. In several cases while the numbers of examinations are given no findings are recorded. Owing to the demands made by routine work and teaching the present staff can spare little time to engage in special research work. In these circumstances it is the intention of Government to place all hospital and laboratory resources of the Medical Department at the disposal of adequately trained research workers who wish to carry out original investigations and steps have been taken to make these decisions known to the incumbents of research scholarships and fellowships in Great Britain, Australia and New Zealand.

Financial—During the year under review expenditure on Medical Services amounted to £84,422 a sum which represents 7.5 per cent of the total revenue of the Colony during the same year.

British Solomon Islands Protectorate (1937)

The British Solomon Islands Protectorate is situated between the parallels of 5°S and 12°30'S., and the meridians of 153 and 170° of E. longitude. It consists of Guadalcanal, Malaita, San Cristoval, New Georgia, Yasabel and other islands east of New Guinea with a total area of about 11 453 sq. miles.

Vital Statistics—The population of the Protectorate in round numbers "remains unchanged, viz Europeans 500 Asiatics 200 and Natives 94 000. Records of births and deaths are not maintained in all Districts, and even where attempts are made to register vital facts, the data for a specific year may be grossly inaccurate for owing to various local circumstances, declarations may not be made until the year following the occurrence of such events as births and deaths. The Report observes "There are no statistics from Santa Cruz, the Eastern Solomon Islands, Malaita, Choiseul, or the Shortland Islands

It is much to be regretted that no figures are available for Malaita the most densely populated of all the group" [In this connexion it is appropriate that mention should be made of the admirable efforts made by the Resident Commissioner Mr F A ASHLEY and of Mr C. N. F. BRACOTT, an Assistant District Officer to secure population and other vital records in these Islands. For some years these enterprising Officers have laboured unceasingly to assemble precise details concerning the populations in Malaita (see this *Bulletin* 1933 Supp. p. 225*) and in the Shortland Islands.] The Protectorate is divided into 8 administrative areas but the Report under review supplies the births and deaths for only 4 Districts, the totals being births 802 deaths 688

Births and deaths records of non-natives are of little value (see this *Bulletin* 1933 Supp. p. 225*) European births numbered 3 and deaths 6 and there were 6 Asiatic births recorded.

European Officials resident numbered 39 with an average number resident of 29 No deaths or invalidings were recorded during 1937

The *labour population* numbered 3 607 and within this group 40 deaths were recorded 19 of the deaths were due to *pneumonia* and 4 to *malaria*

Public Health Sanitation etc—From the health point of view the year was unfavourable mainly on account of the prevalence of respiratory affections which persisted throughout the year Influenza and influenzal colds were always present, the *pneumonias* and other complications were frequent and were responsible for many deaths. Routine *anti malarial* work continued to be carried out and included the weekly oiling and spraying of areas, the routine inspection of houses tanks, gutterings, etc As regards methods of *sewage disposal* the newer residences on Tulagi (the Headquarters of the Resident Commissioner) are equipped with flushing toilets, and either septic tanks or drains discharging into the sea Elsewhere pan latrines are general, while for the use of natives, latrines are built over the sea. *Water supplies* remain unchanged (see this *Bulletin* 1933 Supp. p. 226*) *Plantation labourers* suffered from the prevalent influenza. A new ration scale was approved and will become effective in April, 1938 It is expected that *beriberi* will completely disappear as the result of the adoption of a more generous and properly balanced dietary

Training of Medical and Sanitary Personnel—Four students were under training as Native Medical Practitioners at the Central Medical School Suva Fiji one candidate completed the course and graduated in December 1937 Two natives were trained as *village dressers* at the Tulagi Hospital during the year

Port Health Work—No case of quarantinable disease was reported at any of the three ports of entry During the year 74 vessels entered and 71 cleared from these ports

Hospitals Dispensaries etc—Tabata Hospital on Isabel Island was closed down during the year and Gizo Hospital brought into operation in March The record of work dealt with at hospitals in the Protectorate reads as follows—

Hospital	In patients			Out patients
	Admitted	Treated	Died	
Tulagi	47	49		Averaged 17 daily 3 607 1 439 1,515 —
Europeans	28	29		
Asiatics	625	663	4	
Natives	124	138	20	
Natives only	249	266	6	
Auki	69	69	6	
Aola	2	10	2	
Gizo			1	
Lunatic Asylum				

Of the two *Mission Hospitals* on Malaita one was closed down during the year The Melanesian Mission Hospital at Fauabu continued to do excellent work A new hospital is in course of erection on the island of Kolombangara in the Gizo District by the Seventh Day Adventist Mission. Smaller hospitals in charge of trained nurses have been opened two by the Marist Mission and one by the Melanesian Mission Drugs and surgical supplies were issued by the Medical Department to Mission authorities to the value of £1 108.

Malaria is endemic throughout the Islands no abnormal features call for comment The only details of cases treated are contained in the returns of the Tulagi Hospital viz 14 European 14 Asiatic and 29 Native cases of malaria with 2 deaths (natives) and two non fatal Asiatic cases of *blackwater fever*

Influenza and influenzal colds were a feature of public health experience throughout the year outbreaks which scarcely affect the non native population produce really serious effects among the natives and are the cause of many deaths (see this *Bulletin* 1938 Supp p 226*-227*) At the Tulagi Hospital 155 native and 3 European cases were dealt with none proved fatal

Tuberculosis remains a serious public health problem—made more difficult because patients are unwilling to remain in hospital if they believe they are not improving and because they fail to carry out precautionary measures in their houses and thus spread the infection The returns of the Tulagi Hospital show 20 cases of tuberculosis (all *forms*) and of these 14 were of the *pulmonary* type of the disease even of the latter were native cases The returns also show 22 cases of *pneumonia* with 5 deaths.

BRIT SOLOMON ISLANDS— 228*
GILBERT & ELLICE ISLANDS (1937)

Eight non-fatal cases of *dysentery* (bacillary) were treated in Tulagi Hospital, 6 of *enteritis* and 5 cases of other digestive ailments.

The work of the *yaws* and *hookworm* unit was in abeyance during the greater part of the year (see this *Bulletin* 1938 Supp. p. 227*) but treatments were carried on as usual at Government Stations and by Native Medical Practitioners and drugs were also supplied to Missionaries qualified to give injections, as in past years. At the Tulagi Hospital 64 in-patient cases of *yaws* were treated.

A *leprosy* survey of the Protectorate is in progress conducted by the expert leprologist Dr. James Ross INNES (see this *Bulletin* 1938 vol. 35 p. 882). The work commenced following the arrival of Dr. Innes in August and up to the end of the year three areas had been surveyed—no details are so far available.

General diseases—No case of *syphilis* is mentioned, and the disease is said not to exist among the native population. 20 cases of *gonorrhoea* (all natives) were treated in the Tulagi Hospital.

Scientific—Dr. H. B. HATHERINGTON, Senior Medical Officer mentions the following *special reports* submitted to the Resident Commissioner during the year—

- 1 Survey of State of Nutrition in the British Solomon Islands Protectorate
- 2 Report on Health Organisation and Rural Hygiene in the British Solomon Islands Protectorate
- 3 Report on the Development of Women's Education in the British Solomon Islands Protectorate and their employment in Health Work
- 4 Report on Maternity and Child Welfare in the British Solomon Islands Protectorate

Financial—Total expenditure on Medical and Sanitary Services for the financial year 1936-37 amounted to £9,445 a sum which represented 15 per cent of the Revenue of the Protectorate during the same period.

GILBERT and ELLICE Islands Colony (1937)

These islands, formerly a Protectorate, were annexed to the Empire in November 1915. The Gilbert group lies between 4°N and 3°S. latitude and 172° and 177°E longitude and consists of 16 islands, with several small dependent islets. The Ellice Group, between 8° and 10½°S latitude and 176°E and 179-58°W longitude, comprises 9 islands. Ocean Island (Pagan) is the seat of Government and was proclaimed British in 1900. Fanning Island and, to the north-west of it, Washington Island were included in the Colony in 1916 and Christmas Island in 1919.

Vital Statistics—The following Table has been compiled from the Returns supplied by the various Native Government Scribes—

Race	Population (end of year)	Births	Birth Rate	Deaths	Death Rate	Infant Deaths
Europeans	224	4	18.0	—	—	—
Gilbert Islanders	27,278	1,075	39.1	615	23.2	129
Ellice Islanders	4,283	153	37.1	75	18.2	21
Banabans	679	32	45.5	18	25.6	11
Asiatics	821	2	1.2	3	3.4	—
"Floating Natives"	3,156	?	?	?	?	?
Totals	38,439	1,266	37.3	711	21.0	161

The above birth and death rates are as published in the Report under review but *all would appear to be incorrectly calculated* (see this *Bulletin* 1936 Supp. p. 213* 1937 Supp. p. 219* and 1938 Supp. p. 229*) The correct rates for the different groups appear to be as follows —

Items	Europeans	Gilbert Islanders	Ellice Islanders	Banabans	Asiatics
Birth Rates	18.0	39.4	35.7	47.1	2.4
Death Rates	—	22.5	17.5	26.5	3.6

Maternity and Child Welfare Work—No actual work is reported under this heading. The appointment of a European Matron to the Tarawa Central Hospital was approved when this post is filled steps will be taken to establish a training school for native nurses.

Public Health Sanitation etc—It was generally supposed that the Native Regulations as administered by the Local Native Authorities were sufficient to preserve reasonably decent sanitary conditions throughout the Colony. However the results of village inspections in two islands have exploded this belief and it is possible that the unsatisfactory conditions noted in the two islands are by no means exceptional. Latrines are built on piles over reefs but in many cases such latrines are high and dry except at times of high tide and being near the villages excreta becomes freely exposed to flies. A promising experiment with a modified type of reef latrine is in progress, but it is added that the complete lack of hygienic consciousness among the natives tends to baulk efforts directed towards improving sanitation in the islands. In most islands *water supplies* are obtained from shallow surface wells which are usually unprotected and liable to contamination in two islands rain water is collected into cisterns and used (see this *Bulletin* 1938 Supp. p. 229*).

Port Health Work—Thirteen vessels entered the port of Tarawa during the year one vessel arriving from Hong Kong was quarantined for cholera. At Ocean Island 88 ships entered and were granted pratique.

Hospitals Dispensaries etc—In the absence of information to the contrary it is presumed the numbers and distribution of established hospitals etc remain as previously described (see this *Bulletin* 1938 Supp. p. 229*). During the year the whole position of hospital and dispensary services was thoroughly investigated and it was decided to replace the present unsatisfactory Tarawa Hospital with a larger

modern and fully equipped building and also to provide each island hospital with a dispensary built of imported material to replace the present dusty and often dark little huts used as such. These dispensaries will be erected by personnel of the Medical Department in an attempt to enable the general native community to obtain maximum benefit from the services of the Medical Practitioners while travelling duty when this was possible during the year. They were thus enabled to move from island to island and advise Native Dressers in regard to sanitary matters and the care of hospital patients. Under the arrangement clinical surveys of eight islands having a total population of 15,082 were carried out.

The only details supplied of hospital work are the following —

Hospital	In patients	Deaths	Out patients
Tarawa Central	268	17	4,973
Ocean Island	1,487	78	5,879
Banaban	121	17	483
District (including Funafuti)	441	282	67,101

The Laper is/wm Tarawa was unused until March 1937 (see this Bulletin 1938 Supp. p. 231) when 19 lepers were admitted. Two patients died. It is anticipated that the remainder will be transferred to Malakal Fip.

To the Luvale is/wm Tarawa 4 patients were admitted and 16 were under treatment during the year. Three deaths were recorded, all of them due to dysentery.

Owing to the limited nature of the training of Native Medical Dressers no enumeration of diseases in respect of island hospitals is attempted. The notes which follow briefly refer to some of the principal diseases treated during the year.

The health of the community in general showed no unusual features during the year under review. Several epidemics of influenza were reported among the various islands though none was of particular note. At the British Phosphate Commissioners Hospital, Ocean Island, 7 European and 81 Natives were treated, and at the Tarawa Hospital 9 cases with 1 death were recorded.

As returns in the Report refer to three Hospitals only it will serve the purposes of the present Summary if the principal ailments treated are classified in the following manner —

Disease	Tarawa Hospital	Ocean Island British Phosphate Commissioners Hospital	Banaban Hospital
Dysentery	13	76	23
Diarrhoea and Enteritis	8	179	13
Beriberi	1	48	7
Other deficiency diseases	0	17	—
Rheumatism	1	136	17
Pulmonary Tuberculosis	3	70	4
Bronchitis	—	34	4
Other respiratory diseases	4	47	22
Septic sores	0	264	6
Acroderitis	5	177	5

Tuberculosis—Under this heading it is stated that all forms of tuberculosis though particularly glandular tubercle appear to have shown some increase.

Yaws has shown a definite increase during the year. Native Medical Practitioners and Native Medical Dressers administered 11 044 injections of N A B among a total population of 31 102.

Hookworm is pretty general among the Ellice Islanders. The Native Medical Practitioner stationed in the Islands has trained Dressers in the administration of remedies.

Veneral diseases—It is stated that *sypilis* is unknown but that *gonorrhoea* appears to be increasing.

An investigation to determine the incidence of *filariasis* in the Gilbert Islands was undertaken during the year and continues. The disease is general in the Ellice Islands.

In an *Appendix to the Report* under review Dr T SCHLICHT, Government Medical Officer and Medical Officer to the British Phosphate Commissioners contributes an Annual Medical and Sanitary Report for Ocean Island. The population numbered 2,678 the native birth rate was 33.8 the native death rate 24.6 per 1 000 and the mortality rate for the community as a whole 19.1 per 1 000.

The sanitation of the Island is said to be satisfactory. Salt water *sewerage* is in use in European houses; automatic flush latrines in the British Phosphate Commissioners labourers' locations; *kaustine* systems in the Police lines and prisons and cement slab pits in the Banaban villages. The principal ailments treated in the two Ocean Island Hospitals have been quoted in the Table above. It is stated that *tuberculosis* is not widespread but is very fatal. 14 out of the 55 deaths recorded during the year in the Island were due to this disease. *Yaws* is not common and no cases of *veneral diseases* occurred amongst the inhabitants. *Financial*—No details are supplied.

WEST ATLANTIC

BAHAMAS (1937)

The Bahamas are a chain of coral islands lying between 21°42' and 27°34' N. latitude and 72°40' and 78°5' W. longitude and are the most northerly of the British West Indian Colonies, with the coast of Florida to the north-west and Haiti to the south-east. There are about a score of inhabited islands, of which New Providence is the chief and contains the capital, Nassau. The total area of the archipelago is 4,404 sq. miles, or about half that of Wales.

ital Statistics—The estimated population for 1937 was 68,908. Registered births numbered 2,189 and deaths 1,019; the resulting crude birth and death rates are said to be 36.8 and 17.0 respectively per 1,000 population. On the basis of a population of 68,908 the rates should be for births 32.7 and for deaths 15.2 per 1,000. [In the previous issue of this *Supplement* attention was called to the calculation of these rates for the year 1936.]

It is also noted that live births in New Providence are said to have numbered 676 and in all other islands of the Bahamas 1,428 making a total of 2,104. This figure does not agree with the 2,189 births mentioned above—even if the 105 stillbirths are included agreement is not reached.

Infant deaths are said to have numbered 443 so the infant mortality rate for the whole Colony would be 210.5 per 1,000 live births—for New Providence the rate reads 143 and for all other Bahama Islands 242 per 1,000 live births.

Maternity and Child Welfare Work—An ante-natal clinic was inaugurated as a part of the Out-patients Department of the Bahamas General Hospital; no details are supplied. The ante-natal clinic operated by Roman Catholic Sisters and attended by a private practitioner Dr. M. M. HARR continued to do much useful work. 684 attendances were recorded during the year. Of 676 maternity cases registered in New Providence 396 were delivered at the Bahamas General Hospital. The Infant Welfare section of the Health Department is under the supervision of a specially qualified nurse who contributes a detailed report of the year's work. Three clinics per week are held in the City District and one per month in the Fox Hill District; all clinics were well attended. During the year 1,062 new cases were registered, 10,480 attendances for treatment or advice recorded, and 5,365 home visits paid. During the last three months of their training nurses are attached to the Infant Welfare section to gain practical experience of the work. The course of the training in midwifery has been extended to one year so that midwives in training may spend three months with the Infant Welfare Section.

Provision has been made to subsidize 12 qualified midwives for service in the Out Islands. Eight of these appointments were filled during the year.

School Hygiene—Little information is supplied. The Infant Welfare nurse gave a series of lectures in the senior schools on personal hygiene. Periodic inspection of the Industrial School was carried out by the Assistant Medical Officer who reports that after each visit a persistent gain in weight was noted in the majority of the boys.

Thirty four boys were referred to the Bahamas General Hospital Laboratory for kalin tests three reacted positively and were given appropriate treatment

Public Health Sanitation etc—The health of the Colony remained satisfactory throughout the year. In Nassau a campaign to eradicate mosquito breeding was inaugurated with successful results. Additional connections to the *sewerage systems* were carried out (see this *Bulletin* 1938 Supp. p. 233*). The services concerned with *scavenging* and the *collection and disposal of refuse* functioned satisfactorily as a result of the greater vigilance of Sanitary Inspectors a large increase in the amount of garbage collected is noted. An additional 158 houses were connected up to the chlorinated city *water supply* weekly tests drawn from all districts showed that bacteriologically the water maintains a high standard. A survey of *housing conditions* and sanitation in the slum areas was undertaken and has resulted in the demolition of a number of buildings and a reduction of overcrowding. *Dairies foodshops etc* continued to be inspected at regular intervals no foodshop may now operate without a certificate of the Sanitary Department testifying that the premises comply with the prescribed Sanitary Regulations. Further investigation into the problems of *nutrition and malnutrition* were undertaken by the Chief Medical Officer Dr J. M. CRUIKSHANK (see this *Bulletin* 1938 Supp. p. 234*) and recommendations were made by him with a view to improving existing conditions throughout the Colony. A comprehensive report was submitted to the Welfare Committee suggesting profitable lines of study of nutritional problems for the ensuing year.

The Chief Medical Officer delivered a series of radio broadcasts on the prevention of various diseases which are or may be encountered in the Colony. The Chief Sanitary Inspector contributes his usual annual report of the work of his Department work concerned with the inspection of dairies foodshops housing etc. is described in some detail.

Port Health Work—The Port Officer examines Bills of Health and in cases of doubt a Medical Officer is summoned before a ship is granted pratique. No diseases of a quarantinable nature were reported 749 vessels and 241 aeroplanes were dealt with during the year.

Hospitals Dispensaries etc—The numbers and distribution of patients treated at the various medical institutions during 1937 as given in the Report under review read as follows—

Institution	Admitted	Treated	Died
Alexandra Hospital	2 736	2,822	217
Victoria Jubilee Infirmary	125	200	42
Lazaretto	3	18	1
Mental Hospital	73	132	17
Private Patients Buildings	113	114	6
Totals	3 050	3,286	283

The Report of the Superintendent Bahamas General Hospital states that 3 099 patients were admitted during the year and that 318 hospital deaths were recorded but in the tabulated Returns of this

Hospital admissions are given as 2,259 and deaths 234 [In this connexion see also this Bulletin 1938 Supp., p 234*]

Out-patients treated at the Bahamas General Hospital numbered 15,434 and total treatments (attendances) 33,988. Separate reports on the work of the Out-patients Department and X-Ray Department are appended.

The *training of First Aid Dressers* is carried out at the Bahamas General Hospital. The *Nurses Training Course* has been extended to four years (see this Bulletin 1938 Supp. p 234).

As regards diseases treated during the year it is noted that no case of *malaria*, *dysentery*, *smallpox* or *diphtheria* was recorded.

Eleven cases of *typhoid* and one case of *paratyphoid fever* were reported with two deaths ascribed to the former. Improved water supplies and sanitation plus mass inoculation are combining to reduce the incidence of the disease. *Dysentery* does not appear to be mentioned in the text of the Report but Hospital Returns show 35 cases, distributed as to 30 amoebic, 3 bacillary and 2 unclassified. Two deaths were assigned to the amoebic type of infection, one to bacillary dysentery and one to undefined type.

Of *tuberculosis* (all forms) it is said that 92 cases were admitted to the Bahamas General Hospital with 43 deaths. In another section it is stated that 61 cases of *pulmonary tuberculosis* were admitted. On the other hand the classified returns of the Bahamas General Hospital supply the following data—

Items	Admitted	Treated	Deaths
Pulmonary Tuberculosis	16	71	37
Other forms of T.B.	29	99	6
Totals	35	91	43

Other *respiratory affections* treated during the year include 47 cases of *bronchitis* with one death, and 38 cases of *pneumonia* with 12 deaths.

Pellagra again figures amongst the deficiency diseases treated. 21 patients were admitted, 25 treated and 2 died.

Under the heading *Helminthic Diseases* it is again stated that "Ascaris, oxiurus and trichurus infections are frequently seen. Hospital Returns show 16 cases of ascariasis.

On page 7 of the Report it is stated that two cases of *leprosy* were admitted to the Lazaretto but Hospital Returns record three such admissions. "Alepo" intravenously continues to be the method of treatment.

All the venereal diseases occur—*syphilis*, *gonorrhoea* and *chlamydia* but with great frequency, *chancre* less frequently, and *granuloma venereum* rarely. During the year a survey of the incidence of *syphilis* was undertaken and routine Kahn tests applied to all Hospital admissions with the exception of private patients. Of the 1,621 tests carried out 25.2 per cent. reacted positively. At the V.D. Clinic 783 patients were treated for *syphilis*, 240 for *gonorrhoea*, and 105 for *granuloma venereum*. At the Bahamas General Hospital among

in patients were 189 cases of syphilis 20 soft chancre 43 of gonorrhoea and 7 of granuloma venereum
Scientific—The Report on the year's work at the Government Bacteriological Laboratory is contributed by Dr L. W. FITZMAURICE. The greater part is devoted to details of work concerned with the Venereal Diseases Clinic (see above)
Financial—Expenditure on Medical and Sanitary services during 1937 amounted to £28,965 of which £16,663 were Hospital expenditures

BARBADOS (1937-38)

Barbados the most easterly of the West India Islands is situated in latitude 13° 4' N and longitude 59° 37' W. Its length is 21 miles, its breadth 14 and it has an area about 168 sq miles a little larger than that of the Isle of Wight

General—Dr J. D. ALLEN continued in charge as Acting Chief Medical Officer until Dr B. V. WASE BAILEY assumes his duties as Chief Medical Officer at the end of the current year. No changes of importance in the sanitary organization of the Island are reported and the unsatisfactory arrangements previously described continue (see this Bulletin 1934 Supp p 172* and 1935 Supp pp 212*-213*)
Vital Statistics—For the year ended December 31st 1937 the population of the Island was estimated to number 190,939. Registered births numbered 5,670 and deaths 3,511 the resulting crude birth and death rates being 29.7 and 18.4 per 1,000 inhabitants respectively. Infant deaths numbered 1,228 giving an infant mortality rate of 21.7 per 1,000 registered births. Causes of death are classified by a nomenclature of 85 titles and by sex for each of the eleven parishes and again by the same nomenclature in 14 age-groups. These classifications occupy no less than ten double pages of this small Report of 25 pages.
Maternity and Child Welfare Work—A property adjacent to the General Hospital has been purchased by the Hospital Board with the intention of converting the building into a Maternity ward for hospital cases and an ante-natal clinic

The Infant Welfare Clinic conducted by the Baby Welfare League (see this Bulletin 1938 Supp p 236*) continued to function with excellent results. During the year 385 new babies were entered on the Clinic registers. At the end of the year 472 women were registered under the provisions of the *Midwives and Nurses Registration Act 1921* as midwives only 73 as nurses only and 178 in both capacities. In the classified causes of death the deaths of 48 women were recorded as due to diseases of pregnancy

School Hygiene—Many new buildings have been erected and the sanitary condition of many of the old schools has been improved. The medical inspection of school-children continues results suggest that the services of a dental officer are necessary. The daily distribution of milk and biscuits to the children continues. The Government Industrial Schools (one for boys and one for girls) were satisfactorily managed and the sanitary condition of both institutions is said to be good. No outbreak of epidemic disease was reported and cases of

Illness recorded were of a minor character. Pupils and staffs were given T.A.B. inoculation during the year.

Public Health Sanitation etc.—No important changes in the organization of the public health services of the Island are recorded (see this *Bulletin* 1935 Supp. p. 214* and subsequent issues). The usual Health Week Meetings were held—Lantern lectures and demonstrations were a great success. Lectures on sanitation and health are also given at intervals in different districts by the Sanitation Officer and are well attended.

Port Health Work—In a special Appendix more space is devoted to describing the work of the Port Health Officer than is given in the Report to discussing the sanitation and sanitary administration of the Island as a whole. During the year 142 vessels entered and were boarded by Port Health Officers. 164 were arrivals from ports infected or suspected of being infected with quarantinable diseases. Quarantine measures were enforced against certain territories in the Caribbean Sea and in South America. Passengers arriving for Barbados numbered 9,848 of these 8,237 were medically inspected and 83 placed under surveillance—the majority of them from Venezuela. The trapping and poisoning of rats was continued. 228 rats were bacteriologically examined, all gave negative findings for *P. pestis*.

Hospitals etc.—In general the provision for the care and maintenance of the sick continues along lines previously described (see this *Bulletin* 1935 Supp. pp. 212*-213*). No data are supplied of the cases treated in the General Hospital.

At the *Mental Hospital* 612 patients were in residence at the end of March 1938. Twenty single rooms have been added and 20 are being erected. This additional accommodation will greatly relieve the overcrowding referred to in earlier reports.

At the *Leper Hospital* there were 71 inmates at the beginning of the year. 2 new admissions, 3 re-admissions, 2 discharges and 8 deaths were recorded during the year.

Patients treated in the *Prison Hospital* numbered 179.

The Board of Health Inspectors continued a rigorous search for anopheline mosquitoes. For the past 8 years the Island has been free from malaria.

Of *enteric fever* 138 cases were notified and 34 deaths were ascribed to this cause in the Island as a whole. Energetic steps are taken to discover sources of infection and all contacts are given prophylactic treatment. The Report observes "There has been no diminution in the incidence of *dysentery*, *diarrhoea* or *enteritis* but no statement is appended showing the numbers of cases of these diseases treated. The classified mortality returns show 33 deaths due to *dysentery* and 438 due to *diarrhoea* and *enteritis*—of the latter 406 deaths occurred in the 0-5 age-group.

Notified cases of *tuberculosis* numbered 89 and deaths due to this cause in the Island totalled 277 of the latter 214 were ascribed to the pulmonary form of the disease. Tuberculosis Hospitals have been erected in the parishes of St. Michael and Christ Church.

Seventeen cases of *acute poliomyelitis* were notified during the year these were mild in character and only one death was recorded. There were 12 cases of *diphtheria* with 4 deaths.

Veneral Diseases — During the year under review the *I D Clinic* at the General Hospital was made available for the treatment of in patients. Cases dealt with among in patients and out patients were as follows —

Item	New Cases	Old Cases	Gross attendances
Syphilis	1 008	920	11 580
Gonorrhoea	925	487	16 403
Other V D	43	23	310

In addition to *causes of death* mentioned in the preceding notes other important causes of mortality mentioned in the classified returns include the following *diseases of early infancy* 378 deaths *pneumonia* 250 *nephritis* 244 *cancer and other tumours* 140 and *bronchitis* 100 deaths.

It is said that Government maintain a well equipped and well conducted *Bacteriological Laboratory*. No details are supplied but it is observed the work continues to increase.

Financial — The references to expenditure include the following — *Mental Hospital* £14,291 *Lepor Hospital* £2,582 *Parochial Expenditure on Sanitation* £15,365 and expenditure on *Parochial Poor Law Administration* £43,282.

BERMUDA (1937)

The Bermudas or Somers Islands form a cluster of some 300 small islands in the Western Atlantic in latitude 32 15' N and longitude 64 51' W. The nearest mainland is Cape Hatteras in North Carolina, 530 miles distant. Most of the islands are mere rocks and less than a score are inhabited. The total area is estimated at 19 square miles.

Vital Statistics — The relevant facts may be classified as follows —

Item	Estimated Population	Births	Birth Rate	Deaths	Death Rate	Infant Deaths	I.M.R.
Population—							
White	12,143	211	17.3	117	9.6	11	52.1†
Coloured	18,508	505	26.8	212	11.3	41	81.1
Totals	30,651	716	23.1	329	10.6	52	72.6†

† In the Report these rates are given as 49.3 and 71.4 per 1 000 live births respectively.

The Report contains an interesting commentary upon the longevity experience of the Colony. Since 1866 there have been 29 centenarians in a total of just over 28 000 deaths and of the 28 no fewer than 22 were coloured women. 14 of them dying before 1900. Even allowing for possible inaccuracies in statements of age at death the figures suggest unusual endurance amongst coloured women. The Report

concludes. In these days of studious dietetics there is occasion for us to pause over the survival of these old women, who born into slavery and surviving the lean years of the American Revolution existed on their fish, rice potatoes and rye bread to the greatest age our records show or are likely to show.

Maternity and Child Welfare Work—The 9 District Nurses and 1 relief nurse of the Bermuda Welfare Society paid 1,560 ante-natal visits and attended 268 maternity cases to these figures must be added 2,567 visits to the Baby Clinics (see this *Bulletin* 1933 Supp p 238*). The nurse of the Hamilton Parish Nursing Association made 3,228 home and clinic visits and attended 34 maternity cases.

The Public Health Act provides for instruction in contraception (see this *Bulletin* 1933 Supp p 238*). During the year six meetings were held to launch the idea of birth control and were well attended.

School Hygiene—Dr J P SWEENEY examined 700 school-children in the western parishes. He reports fewer cases of scabies and impetigo than in former years, but more of *pediculosis capitis*. In the Central parishes 811 white and 1,157 coloured children were examined for the first time. Lack of cleanliness was observed. Extensive dental work was undertaken over 600 children were given dental treatment, but the percentages for non-attendance for and refusals to undergo treatments were high. Dr Sweeney immunized 100 children in the Western parishes against diphtheria. Opposition was experienced in both the western and central areas against immunization. Dr W E TALBOT reported that 15 per cent. of the children of West Indian parents attending the Central School showed umbilical hernia. The condition was not seen elsewhere.

Public Health Sanitation etc—Dr H WILLIAMS contributes a brief survey of progress characterizing Public Health work in Bermuda during the past eight years. The control of flies and mosquitoes is being seriously attempted. Swampy areas are being reclaimed by the dumping of rubbish and steel drums are being supplied to the public for use as incinerators. Methods of sewage disposal remain as previously described (see this *Bulletin* 1933 Supp p 239). At St. George's a well was sunk to supplement supplies for the flushing of toilets in the Queen Street area. Proposals to clear St. George's of its sanitary antiquities overhanging the waterfront were repelled by the Corporation. The revised Public Health Act which became effective on the 1st of February 1938 provides for a more adequate storage of water and limits the capacity of a dwelling for human occupation to the quantity of water available to keep those occupants clean. By encouragement and competition great improvement in the condition of dairies and milk supplies is reported. Dr J C COOPER, Government Veterinary Officer, tuberculin-tested 1,769 dairy cattle and found 42 reactors. In the Central District 916 cattle were tested for contagious abortion when 60 showed definite and 109 slight infection. In the Western District where 62 cattle were examined, the corresponding findings were 7 and 25 respectively. The inspection of grocery stores and of locally killed meat was continued. It may be noted that the Public Health Act provides for the periodic examination of all persons employed in handling the food and drink of others and of all servants employed in any restaurant, hotel, guest or boarding-house."

A classified return of the numbers and nature of sanitary inspections carried out under the provision of the Public Health Act is supplied.

Port Health Work—The information supplied relates to the arrival of 83,092 passengers of the total 731 arrived by air.

Hospitals Dispensaries etc—The *Bermuda Collage Hospital Nursing Home* (see this *Bulletin* 1938 Supp. p. 239*) received a grant of £1,500 from the Treasury. The 150 patients treated included 5 maternity cases. Nurses paid 58 visits to homes during the course of the year. Considerable extensions are being made to the *King Edward VII Memorial Hospital*. No admissions to the *Isolation Hospital* were recorded during 1937.

Weekly clinics were maintained at two centres by Dr. J. P. Sweeney and by Dr. W. H. C. MASTERS at three centres during the year.

Dr. Wilkinson observes that the chronic ailments of the circulatory system and kidneys preponderate in the Colony. In the classified returns 83 deaths were ascribed to diseases of the circulatory system and 25 to diseases of the genito-urinary system (24 of these to nephritis alone).

For the first time in a long while the fear of communicable disease has shaken the equanimity of this Colony. This observation doubtless refers to the 7 cases of anterior poliomyelitis notified—the first case occurring in one of the cadets on board H.M.S. *Trobisher*. Dr. W. Lloyd Aycock of the Harvard Medical School and Chief of the Commission on Poliomyelitis in Massachusetts investigated the sporadic cases following the first case notified.

Of the 12 cases of tuberculosis (all forms) recorded 11 were of the pulmonary type of the disease. 9 deaths were ascribed to pulmonary tuberculosis and one to other forms of tuberculosis during the year under review. The Tuberculosis Pavilion has not yet progressed beyond a plan (see this *Bulletin* 1938 Supp. p. 240*) owing to the fact that extensions to the main hospital must first be completed.

A ship from South America had one case of smallpox on board. No other cases were reported. During the year 503 vaccinations were performed. Conscientious objectors numbered 155.

Other communicable diseases notified included 39 cases of scarlet fever, 35 of chickenpox, 24 of measles and 24 of German measles and two of typhoid fever. No deaths were assigned to any of these titles. It is noted that 24 deaths were assigned to cancer and 3 to other tumours.

The Venereal Diseases Clinic at the Hospital continued to function one afternoon each week with an average attendance of about ten. Drs. Sweeney and Masters also maintained clinics in their districts and Dr. Masters attended gaol prisoners who were in need of treatment. The Public Health Act will give the Board of Health some control of those who habitually spread venereal diseases.

Financial—Expenditure on Medical and Health Department services amounted to £14,588 and on the Isolation Hospital £1,884. These sums in the aggregate represent 3.6 per cent. of the total expenditure or 3.5 per cent. of the revenue of the Colony during the year under review.

BRITISH GUIANA (1937)

British Guiana the only British Colony on the mainland of the South American Continent, lies on the north-eastern coast. Its seaboard, about 270 miles extends almost from the eastern mouth of the River Orinoco to the River Courantyne, and has to the north the Atlantic Ocean to the south and south-west Brazil, to the east Dutch Guiana and to the north-west Venezuela. Its area is approximately 89 44 square miles (a little more than England, Scotland and Wales together). Its capital is Georgetown, the next most important town being New Amsterdam, about 60 miles east of Georgetown.

Vital Statistics—The welcome and informative feature introduced in the Annual Report for 1935 under the title of *Comments on Vital Statistics* is continued in the Report under review. The relevant facts are classified in great detail for each Registration District in the Colony but for present purposes the following summary must suffice—

Item	Estimated Population	Births	Birth Rate	Deaths	Death Rate	Infant Deaths	I M I
The Colony	337 039	11,227	33.3	7,367	21.9	1,359	1.1
Georgetown—							
Municipal Area	64,200	1,801	28.0	1,302	20.3	—	109
Registration Area	67 448	2,103	31.3	1,396	20.7	217	103
New Amsterdam	9 650	338	35.0	210	21.8	33	104

The average population of the *Maturum Diamond Fields* was 3,993. Births registered (all being aboriginal Indians) numbered 5 and deaths 36. No population figures are given for the *Sugar Estates* though on these properties 2,379 births and 1,343 deaths were registered, while the infant mortality rate for 1937 is stated to have been 111.3.

Maternity and Child Welfare Work—Details of the year's work carried out in the maternity wards of the five principal hospitals in the Colony can be summarized as follows—

Hospital	Bed Accommodation	Deliveries	† Births	Maternal Deaths
Georgetown	46	1 064	927	36
New Amsterdam	8	227	203	11
Soddu	1	73	67	6
Maharuma	2	32	31	—
Bartica	9	16	13	—

† Presumably live births.

The activities of the *Infant Welfare and Maternity League* were maintained throughout the Colony. League nurses attended 2,445 confinements and recorded 2,358 live births during the year. Clinics were conducted by Government Medical Officers and in remote areas by Government Dispensers at 60 centres (see this *Bulletin* 1937 Supp. pp. 230*–231*). At these centres 1,090 clinics were held during the year and 4 416 infants and 1 676 expectant mothers were

treated. In accordance with usual practice the League received the financial support of Government from these funds were subsidized seven health visitors and 41 nurse midwives stationed in the more populous centres of the Colony and in remote river and creek areas. A further sum of money part of the total contributions to the King George V Silver Jubilee Fund was handed over to the League to be expended on as many couch-cabinets as possible to be distributed to the various clinics throughout the Colony. The training of midwives continues (see *Hospitals* below).

Maternity and child welfare work continues to make good progress on the *Sugar Estates*. Clinics are conducted by Government and Estate Medical Officers nurses and midwives. 22 Estate Hospitals are now provided with maternity wards.

School Hygiene—References which can be assigned to this heading mainly relate to the dental treatment of school-children. Dental clinics were conducted in Georgetown and New Amsterdam. It is said the School Dental Scheme continues to be highly appreciated both by pupils and parents. In 1938 an experimental scheme of milk distribution to selected groups of school-children is to be inaugurated. In a short report on the Industrial School Onderneeming (average number of boys 77) it is stated the general health of the boys was satisfactory sanitary arrangements were satisfactory and sanitation was well maintained.

Public Health Sanitation etc—The Report under review on the health and sanitary conditions of British Guiana for 1937 is dated "1st of March 1939" and submitted by Dr A. J. MACLENNAN who succeeded Dr J. A. HENDERSON as Surgeon-General. [This title was changed to that of *Director of Medical Services* by Ordinance No 11 of 1938.] Dr Henderson left the Colony in June 1937 and thenceforward to the end of the year Dr B. A. V. WASE BAILEY Government Medical Officer of Health acted as Surgeon-General.

With regard to *anti malarial measures* it is reported that the bonification of the Thomas Lands (see this *Bulletin* 1936 Supp p 226* and 1937 Supp p 233*) was continued. Special emphasis is laid upon the importance of adequate drainage along the coast-lands of the Colony in connexion with the prevention of malaria. In the absence of specific descriptions it is assumed that methods of *sewage and refuse disposal* remain as previously described. Efforts are continuously made to improve the sanitary conditions in all areas and the classified returns of the work carried out by District Sanitary Officers indicate that a large number of new latrines were erected (see this *Bulletin* 1937 Supp p 231*). The only references to *water supplies* appear to relate to improvements completed on *Sugar Estates* to available supplies to the Leprosy Hospital and to water examinations carried out at the Government and Health Department Laboratories.

There was no change during the year in the arrangements for the medical and sanitary care of *Sugar Estates* (see also *Scientific* below) and *Mining Properties* (see this *Bulletin* 1937 Supp p 231*-232*).

The routine inspections of premises concerned with the manufacture and sale of *foods and drinks* were continued, and the question of *milk supplies* received special attention. The great difficulty in the control of supplies lies in the absence of large farms where milk production is the primary object and the presence of a very large number of

small producers. The *Report of the Nutrition Committee* was published as Sessional Paper No 3 of 1937. It discusses such matters as soil, water and food products, analysis of foodstuffs, racial and dietetic habits, educational and economic aspects of nutritional problems, etc.

The Central Board of Health devotes special attention to housing and the proper laying out of land for building purposes. Progress is reported, particularly in the County of Berbice where conditions were notably unsatisfactory. Special reference is made to the patience and assiduity of *District Sanitary Inspectors*. Details of the work carried out by these Officers are presented in an Appendix.

Port Health Work.—Quarantine was permanently maintained during the year against all South and Central American Ports (except British, French and Dutch) against New Orleans, Mobile and Tampa (U.S.A.) for a specified period and against ships arriving from certain ports in the Caribbean Sea to ensure the notification of the occurrence of quarantinable diseases. During the year the Port Sanitary Inspector paid 490 visits to 204 steamers and 553 visits to 298 sailing vessels, while the Port Health Officer visited 139 vessels and placed 63 passengers under surveillance for smallpox. Plague precautions were enforced upon vessels lying alongside wharves and the trapping and examination of rats was continued. Only 4 rats were trapped during the year, none was infected with *P. pestis*.

Hospitals, Dispensaries, etc.—Considerable space is devoted to describing the year's work at the various Government Institutions and in addition to extensive textual commentaries, the relevant facts are set out in great detail. For the seven Public Hospitals in the Colony the data relating to in-patients, hospital deaths, and out-patients are tabulated for each hospital according to a disease nomenclature of 205 titles—some of these having several sub-divisions. [This extensive classification appears to be unnecessary for the purpose of an Annual Report and is rather wasteful of time and money necessary for preparation, and cost of printing. It is suggested that the special Colonial nomenclature of 65 titles would meet ordinary requirements.] As regards other institutions the information supplied is equally comprehensive. For purposes of convenience the relevant data are summarized below:—

Institution	In-patients treated	Hospital Deaths	Out-patients
<i>Public Hospitals—</i>			
Georgetown	13,830	1,214	32,862
New Amsterdam	3,230	268	13,899
Saddis	2,017	186	4,618
Berbice	627	62	3,199
Labaruma	514	46	1,591
Kamukma	45	1	1,078
Potaro	19	3	627
Totals	20,298	1,796	57,797
<i>Other Institution</i>			
Mental Hospital	823	97	Remaining at end of year 707
Alms House	141	234	856
Three Prisons	109	—	?

In addition to the Out patient departments of the seven Public Hospitals there is a Government Public Dispensary in Georgetown and 13 Government Dispensaries in the charge of qualified sick nurses and dispensers established in remote yet populous river districts and in the mining areas. At these 14 Dispensaries 42 354 patients were treated during the year and of these 30,356 were new cases.

So far as *Hinterland Settlements* are concerned special arrangements suited to local conditions are made to provide the inhabitants with medical aid. Free medicines are supplied to a number of *Aboriginal Indian Stations* the personnel of *Mission Stations* are particularly successful in dealing with the inhabitants of these areas. Periodical visits are paid by the Government Medical Officer Skeldon to a settlement up the Courantyne River (along the borders of Dutch Guiana). For the medical aid of residents in the Rupununi area (a remote district in the south west of the Colony bordering Brazil) a Government dispensary was established at Kurupukarra in September 1937 in charge of a dispenser. This man acts also as primary school teacher, cattle-trail clerk, and during school holidays is expected to make first aid tours to the settlements in the area!

The training of nurses is carried out at the Government hospitals in Georgetown, New Amsterdam and Suddie. At the Nurses examination held in June 1937 nineteen nurses sat for the First Professional and 26 for the Final examination. 13 of the former and 22 of the latter were successful. Out of 32 pupil midwives who sat for the Midwifery examination 20 were successful.

Hospitals and dispensaries are maintained on 23 (out of 31 plantations) *Sugar Estates*. Hospital in patients numbered 24 235, hospital deaths 851, and 6 331 patients were treated at the dispensaries.

A hospital of 8 beds is established at the headquarters station of the *Malarami Diamond Fields*; a dispensary is attached to this hospital and another at an out-station.

The textual comments upon the incidence and distribution of disease in the Colony are mainly based upon the returns of hospitals and dispensaries.

Malaria remains the Colony's most important disease and is responsible for about 750 deaths each year. During 1937 registered deaths ascribed to this cause numbered 755 and in addition there were 327 deaths due to *undefined fevers*. Hospital in patients treated for malaria numbered 2 169 and of these 125 died; there were also 9,312 out patients treated for the disease. Eight in patient cases of *Blackwater fever* with 2 deaths were reported. Types of infection were as follows:—

Type of infection	In-patients	Deaths	Out patients
Benign tertian	150	4	220
Quartan	1	—	—
Subtertian	64	10	11
Chronic malaria	248	17	732
Unclassified	1 708	94	8 349
Blackwater fever	8	2	—

At the Government Laboratory 1,053 blood films were examined and the following positive findings recorded *P. vivax* 154 *P. falciparum* 48, *P. malariae* 2.

In *Sugar Estate Hospitals* 10 419 cases of malaria were treated with 142 deaths. Malaria is also the chief cause of disability in Mining areas on the Mazaruni Diamond Fields 7 deaths were ascribed to the disease.

Filaria (and filarial bubo) gave rise to 281 in-patient cases and 12 hospital deaths and in addition there were 602 out patient cases of filariasis and 5 of filarial bubo. Deaths in the Colony ascribed to filariasis numbered 32. As regards *elephantiasis* there were 21 in patients and 22 out patients treated for this condition no deaths were ascribed to this cause.

Of *enteric fever* 329 cases were notified with 65 deaths. Cases treated as hospital in-patients numbered 254 (253 typhoid 1 paratyphoid A) with 42 deaths. At the Laboratory 328 Widal examinations were made the positive findings recorded were *Bact. typhosum* 107 *Bact. paratyphosum A* and *B* each 11 and *Bact. paratyphosum C* 6. In addition to the Widal tests, 549 faecal specimens were cultured and *Bact. typhosum* isolated in 60 cases.

In patient cases of *dysentery* numbered 129 distributed as to 46 amoebic 4 bacillary and 79 unclassified. In addition there were 134 out patients. Total deaths in the Colony ascribed to dysentery numbered 113 and of these 23 occurred in hospitals. At the Laboratory *E. histolytica* was found in 18 of 797 specimens of faeces examined while in the course of cultural examination of 140 faecal specimens *Bact. dysenteriae* Flexner was identified in two cases. *Diarrhoea and enteritis* caused the deaths of 369 persons in the Colony during 1937 and 67 of these deaths occurred in hospitals. in-patients treated for diarrhoea, enteritis, and colitis numbered 407 and out patients 699.

Notified cases of *tuberculosis* (all forms) numbered 325 and 298 deaths were ascribed to this cause in the Colony as a whole. It is noted that of 530 hospital in-patient cases dealt with of which 197 terminated fatally 502 of the hospital cases and 182 of the hospital deaths were due to the *pulmonary* form of the disease. At the Laboratory 736 specimens of sputum were examined and 191 were positive with *Mycobacterium tuberculosis*. The site for the new Tuberculosis Hospital has been prepared and building operations are to commence. Meanwhile the British Guiana Society for the Prevention and Treatment of Tuberculosis continued its activities as in former years.

Other respiratory affections treated at hospitals, etc., included the following —

Disease	In-patients	Deaths	Out patients
Bronchitis	584	40	3,911
Broncho-pneumonia	73	47	9
Pneumonia	246	140	32

Askylostomiasis appears to be the most common helminthic infection. Hospital in-patients treated for this condition numbered 83 (2 deaths) and out-patients 80. In patients treated for *ascariasis* numbered 13 and out-patients 96. At the Government Laboratory 797 faecal

specimens were microscopically examined and the following positive findings recorded —

Ova of *Ancylostoma* in 149 of *Ascaris* in 29 of *Trichuris* in 14, of *Enterobius* in 1

Leprosy — In accordance with usual practice extracts from the annual report of Dr F G ROSE Medical Superintendent of the Leprosy Hospital are presented. It is not always easy to follow the numerical statements presented with reference to Leprosy in British Guiana. In one statement it is said 46 patients were admitted to the Leprosy Hospital during 1937 (14 being former out patients). Again of 635 cases of leprosy known to the authorities and believed to be alive it is said 392 were inmates of the Leprosy Hospital. But at the beginning of the year there were 374 inmates 46 were admitted (or 32—see above) apart from 82 re admissions according to a tabular statement which also announces that there remain 375 lepers still in residence at the end of the year. Among these 375 patients were 18 Europeans 104 East Indians 6 Chinese 187 Black and 60 persons of mixed descent.

Veneral Diseases — The V D Clinic at the Public Hospital Georgetown continued to extend its activities during the year while in the Public Hospitals of New Amsterdam and Suddie and to a lesser extent in Bartica limited provision for such work has been made. It is hoped to provide a scheme which will embrace the villages and plantations throughout the Colony and permit the appointment of a whole-time Assistant V D Officer for the organization and control of clinics in outlying areas.

The Report under review supplies a comprehensive account of the year's work and numerous tabulated statements relating to numbers of patients with distinction of sex and age in conjunction with the type of venereal disease. These statements may be summarized to read as follows —

Disease	Government Treatment Centres		Treated on Sugar Estates	
	In patients	Out patients (new cases)†	In patients	Out patients (new cases)†
Syphilis	559	1 002	67	104
Gonococcal infections	646	1 376	104	74
Granuloma Venereum	83	49	2	1
Soft Chancres	89	63	3	5

† In the 1937 issue of this Supplement out patient attendances were recorded.

Extracts of some length are presented from the annual report of Dr E G H PAYNE Medical Officer in charge of the V D Clinic Georgetown.

At the Laboratory out of a total of 14 480 specimens dealt with Wassermann reactions totalled 6 460 and of these 1 656 gave positive findings. In addition 2,333 smears were examined for gonococci but findings are not recorded.

Eleven in-patient and 22 out patient cases of yaws were treated during the year under review

Among other diseases referred to in the Report the following call for brief mention. The *Report of the Ophthalmic Department* states that 388 in-patients and 5 068 out patients were treated for eye diseases, but the returns relating to the seven Public Hospitals show that 607 in-patients and 2,871 out patients were treated for affections of the organs of vision. Nephritis caused the deaths of 628 persons in the Colony in 1937 for this disease 558 in patients (111 deaths) and 574 out-patients were treated in Public Hospitals. For cancer 150 persons were treated as hospital in-patients and 42 died, while in the Colony as a whole the deaths of 147 persons were ascribed to this cause.

[The nomenclature used for the classification of diseases treated in hospitals remains unchanged though considerably out of date for comparable purposes see this *Bulletin* 1937 Supp. p. 235*.]

Scientific—The Annual Report of the Government Laboratory describes the number and nature of the specimens received reference has been made to many of these findings in the preceding notes.

The outstanding public health effort in 1937 was the establishment of a Central Medical Research Laboratory which was opened in Georgetown during August by certain of the Sugar Producers in the Colony. This Laboratory is under the direction of Dr G. GIGLIOLI (see this *Bulletin* 1936 Supp. p. 228*) who will investigate medical and sanitary problems peculiar to plantations and which adversely affect their resident populations. The experience derived from this venture will undoubtedly prove of value to the health of the Colony at large.

Financial—Total expenditure on Medical and Health Services during 1937 amounted to \$554 000 a sum which represents 8.4 per cent. of the total revenue of the Colony during the same year.

BRITISH HONDURAS (1937)

British Honduras is on the east coast of Central America, with Yucatan (Mexico) on the north and north-west and Guatemala on the west and south and on the east the Bay of Honduras (Caribbean Sea). It has an area of about 8,598 sq. miles, i.e. about the size of Wales.

Vital Statistics—The relevant facts for each of the six Districts and for the Colony as a whole are presented as follows—

District	Estimated Population	Births	Birth Rate	Deaths	Death Rate	Infant Deaths	1 M R.
Belize	22 015	750	34.0	418	18.9	94	125.3
Corozal	8 199	261	31.8	181	22.0	49	167.7
Orange Walk	6,153†	183	29.0	117	17.9	20	109.2
Stann Creek	6,349	176	27.7	77	12.1	18	85.2
Toledo	6,430	274	42.6	154	23.6	29	102.1
Cayo	7 387	232	31.4	109	14.7	24	103.4
The Colony	66,893†	1,876	32.9	1 054	18.6	230	122.6

[† It will be noted that the District population figures do not aggregate 56,893 as given, and that the birth and death rates for *Orange Walk* are incorrect on the basis of population of 6,153. What has happened is that a printer's error has crept in transposing the population figures for Orange Walk which should read 6,613 to make the Colony total as stated.]

Figures showing the numbers resident invaliding and death rates of *European and Native Officials* are not available as these Officials are attended by Private Medical Practitioners

Maternity and Child Welfare Work—A considerable amount of information appears under this heading in the Report under review for in addition to a general survey of the work in the Colony as a whole almost without exception the Reports of District Medical Officers describe activities and progress in the areas for which they are severally responsible. Infant welfare appears to be well provided for but in some areas no facilities exist for ante natal supervision or hospital treatment of maternity cases in the absence of trained midwives the practice of irregular midwifery is by no means uncommon in the Districts. On the other hand it is noted that a Maternity Ward and Infant Welfare Centre were completed at the Stann Creek Hospital during the year.

There are *Infant Welfare Clinics* established in all Districts operated by Government Medical Officers and Head Nurses with the assistance of ladies in the various areas. The volume of work dealt with at these Centres may be summarized as follows—

District	Children on Registers	Average weekly Attendances	Health Visits
Belize	1 832	150	1 649
Corozal	158	30 55	?
Orange Walk	?	25 30	?
Stann Creek	280	20 25	?
Toledo	171	48 50	?
El Cayo	200	40	?

Reference is made to the amount of irregular midwifery practised in some areas and surprise is expressed that not more gross infection at childbirth is met with. Hospital Returns show under *Toxaemias of Pregnancy* that 23 cases were treated with 5 deaths.

School Hygiene—The medical examination of school-children in Belize has been systematically organized and during the year 2 119 children were examined. Detailed analyses of findings will be supplied in future Reports but for the year under review general impressions only are recorded. The *spleen rate* was 2.4 per cent. evidence of clinical *anaemia* of a mild type was observed and *pyodermites* seemed to be common. The Reports of four District Medical Officers refer to School Hygiene in their respective areas. In El Cayo District children were well nourished and the spleen index was low. The Stann Creek Report provides considerable detail. 841 children were examined and 22.6 per cent had enlarged spleens. height and weight tables and graphs with age and sex distinction are a feature. The medical examination of school children has been started in town and village schools in Corozal District and in Orange Walk District. Dr B E WASHBURN of the Rockefeller Foundation visited the Colony in October and remarked upon the healthy condition of school children seen in Belize.

Public Health Sanitation etc—Dr R. L. CHEVERTON Senior Medical Officer reports the health of the Colony continues to improve with improvements especially noticeable in the state of the nutrition of children. Organization of health services for administrative purposes remains as previously described (see this *Bulletin* 1935 Supp., p. 227*) but certain proposals for the reorganization of the Medical Department have been submitted for Government consideration. Meanwhile the advice of the International Health Division of the Rockefeller Foundation in regard to problems of public health in the Colony was sought, and in February Dr BOYD arrived to discuss with the responsible authorities a comprehensive scheme which had been prepared in anticipation of his visit.

Methods of sewage disposal remain for all practical purposes unchanged (see this *Bulletin* 1938 Supp. p. 241*). Considerable improvement could be made in refuse disposal systems in Belize and other towns. In the villages no system obtains and villages are described as being in "a filthy state". Sources of water supply remain as described in the previous issue of this Supplement.

With regard to housing the Report observes that on the whole the design of the houses is quite unsuitable for a hot humid climate. In Belize there are twenty slum areas where conditions become worse from year to year. A scheme for slum clearance has been submitted to the Local Authority.

The Reports of District Medical Officers which appear as Appendices to the Annual Report under review discuss general sanitation, water supplies etc. in the respective areas.

It is noted that the Medical Department has not a single Sanitary Inspector under its control, all Sanitary Inspectors being a charge on Local Authorities and therefore under the direct control of laymen on the Committees of Local Authorities.

The Report of the Senior Sanitary Inspector Belize supplies a detailed account of the work performed by Sanitary Inspectors during the year.

Dr Cheverton's recommendations for future work include (a) Reorganization of the Medical Department (b) Training of local Sanitary staff and general sanitation to be under the control of the Medical Department (c) A tuberculous survey (d) a malaria survey (e) An anti-hookworm campaign (f) Rebuilding of certain Hospitals and improvements to others, (g) Extension of Infant Welfare Work, (h) Dental services, (k) Dietary survey.

Port Health Work—Quarantine regulations were again in force against Central American Republics. People who cross the frontiers of the Colony at uncontrolled places are a source of danger while aerial traffic between the Colony and Mexico and Spanish Honduras increase the quarantine problems especially with regard to the possible introduction of yellow fever.

Hospitals Dispensaries etc—An Eye Department was added to the Belize Hospital, and a four-bed Maternity Ward to the Stamm Creek Hospital—no other changes are recorded. Plans for a new and larger hospital in Belize are in course of preparation. Several hospitals are in urgent need of extensive repairs. The volume of work dealt with during the year at the six Hospitals in the Colony may be summarized as follows—

Hospital	Beds	In patients	Deaths	Out patients
Belize	62	1 775	111	22 734 attendances
Corozal	20	270	14	No information given.
El Cuyo	12	234	7	
Orange Walk	11	151	12	1,340 patients attended Some 2,000
Stann Creek	20	484	22	
Toledo	8	326	8	

The figures for in patients and hospital deaths were extracted from the classified returns but these are not always in agreement with statements contained in the Reports of District Medical Officers. For example the Hospital Returns for Corozal show 270 in patients treated with 14 deaths but the District Medical Officer mentions 320 admissions and 22 deaths.

The training of nurses is undertaken at the Belize Hospital the course extending over a period of three years. Trained nurses are gradually replacing untrained ward maids in the District Hospitals.

The diseases which occupy the Medical Department to the greatest extent are malaria, helminthiasis, venereal diseases, deficiency diseases and pulmonary tuberculosis.

Malaria is a real economic problem neither Government nor employers of labour have so far devoted sufficient consideration to the principal cause of disability in the Colony. The classified Hospital Returns show that 758 cases of the disease were treated (in patients) with 26 deaths the distribution of types of infection being *benign tertian* 141, *quartan* 4, *subtertian* 146 and *unclassified* 467. Here again statements appearing in Hospital Returns are not always in agreement with Reports of District Medical Officers. The vector or vectors of malaria in the Colony are unknown though *A. albimanus* is thought to be primarily responsible. In this connexion the Medical Officer Stann Creek in the course of an excellent discussion of the malaria problem in this District observes: "The position of a Medical Officer is not enviable when he has to deal with malaria in a locality where the anophelines of the area are unknown, the various species that carry malaria are unknown and no technical assistance available to examine blood films of every patient." Nine cases of blackwater fever with one death are recorded.

The usual preventive measures were carried out but these are described as totally inadequate through lack of funds and lack of knowledge of the habitat of the infective vector. It is hoped that the visit and advice of Dr Boyd of the Rockefeller Foundation (see above *Public Health*) will serve to focus attention on the malaria problem and lead to the provision of services necessary to effect improvement in existing conditions.

No case of yellow fever has been recorded since 1921 but the increase in the *Aedes* index in Belize is said to be alarming. Despite all measures surveys show a high incidence of mosquito breeding (see this *Bulletin* 1938 Supp. pp 242*-243*). In a section of the Report which discusses malaria the following remarks appear:—A tendency to bleeding (renal and bowel) has been observed and in some cases ultimately developing blackwater fever manifesting signs of allergy, urticaria,

On the other hand, it is difficult to place some cases of grave jaundice (leptospirosis area of Yellow Fever?)

Alastrim is the only form of smallpox seen in the Colony and during the year 57 cases were recorded. It is believed that the original infection was introduced from Mexico. Regular vaccinations were carried out by Medical Officers and Public Vaccinators in towns and villages and 1 032 children under the age of five were successfully vaccinated.

No case of *enteric fever* was notified but of *dysentery* the Report observes "108 cases were treated in the various Hospitals during the year with 5 deaths." Actually Hospital Returns show 110 cases distributed as to 67 *amoebic* 19 *bacillary* and 24 unclassified. The responsible factors are again referred to (see this *Bulletin* 1938 Supp. p 243*).

Pulmonary tuberculosis continues to cause concern but apart from the returns of certified deaths, it is difficult to estimate the extent of the disease. During the year 29 deaths were certified as due to this cause but there were also 17 deaths (uncertified) ascribed to "consumption," "cough" or "cold." Among 48 cases (all forms) treated in Hospital with 7 deaths, 38 of the cases and 6 of the deaths were due to the *pulmonary* form of the disease. The *pneumonias* were responsible for 51 Hospital cases and 12 deaths.

Helminthiasis is described as "a potent source of chronic invalidism especially among the Mayan and Spanish elements; most children seem to be subject to worm infestation. *Achylostomiasis* is said to be prevalent in all districts. In-patients treated for the disease numbered 37 but it is noted that all except seven cases are dealt with as out patients and of these no data are supplied. The Medical Officer Stann Creek, observes, "The solution is again an economic one as both private latrines and the wearing of shoes require money. (See this *Bulletin* 1938 Supp. p 243*.)

Veneral Diseases which are extremely prevalent have so far received only spasmodic attention partly owing to lack of funds for specific treatment but more particularly owing to the apathy of the average person in seeking proper and adequate attention. In patients treated for syphilis numbered 100 for gonorrhoea 81 and for other forms of V.D. 44. The majority of District Medical Officers discuss the problem of social hygiene in their respective areas, the contribution of Dr L. M. RAM of Stann Creek calling for particular mention. The increased amount of labour employed in the mahogany camps in the Corozal and Orange Walk Districts was largely responsible for the increase in the numbers of cases in these areas.

Other diseases referred to in the Report under review and calling for brief mention in this Summary include the following. *Deficiency diseases* are more apparent than formerly and although Hospital Returns show only 4 cases of scurvy 2 of beriberi 4 of pellagra and 33 of other forms of *avitaminosis* nearly all District Medical Officers have something to say about malnutrition and its effects. In Toledo District *nutritional anaemia* and *macrocytic anaemia* of pregnancy are said to be very common. Dr RAM of Stann Creek discusses the diets of Caribs and Creoles, the existence of deficiency diseases and nutrition as judged by physical measurements. Dr D. W. DEGAZON of Corozal District also speaks of village diets and of the

investigation of a few cases treated in his Hospital. The whole question of nutrition has been discussed in a Report prepared in collaboration with the Agricultural Department and submitted to the Secretary of State.

One case of *relapsing fever* and one of *anterior poliomyelitis* are recorded in the Hospital Returns. Several cases of the latter disease are said to have been reported by local practitioners. Sporadic outbreaks of *nephritis* among children are mentioned. 45 cases of *nephritis* were treated in Hospitals. *Skin diseases* are very prevalent and are responsible for a considerable number of Hospital in-patients. The Report states that 54 cases of *cancer* were treated during the year but Hospital Returns show 30 cases of malignant disease with 6 deaths, 16 non-fatal cases of non-malignant tumours and 8 unclassified cases with 3 deaths.

Financial—Expenditure on Medical Department services during 1937 amounted to \$89,654.

JAMAICA (1937)

Jamaica, an island in the Caribbean Sea about 90 miles south of Cuba within 17°42' and 18°32' N. latitude and 76°11' and 79°23' W. longitude. It is the largest of the British West Indian Islands, being 144 miles long and 60 at its greatest breadth and having an area of 4,450 sq. miles, or about half that of Wales. Kingston, the capital, is on the south coast in the County of Surrey. The Cayman Islands and the Turks and Caicos Islands are dependencies of Jamaica.

Vital Statistics—The estimated population at the end of the year was 1,152,528. Estimated population figures are given for each of the 15 Parishes in the Island. Registered births numbered 35,362 and deaths 17,481, the resulting birth and death rates being 32.1 and 15.3 per 1,000 population respectively. It is noted that the death rate for 1937 was the lowest on record in the Island. The *infant mortality rate* is stated to have been 119 per 1,000 live births. The principal causes of death arranged in descending order of importance were *undefined fevers* 1,834, *congenital debility* 1,415, *infantile convulsions* (under 5 years of age) 1,255, *pulmonary tuberculosis* 1,019.

Maternity and Child Welfare Work—The ineffectiveness of the provisions for parochial maternity work was discussed in the Annual Report for 1936 (see this *Bulletin* 1936 Supp. pp. 244*-245*). Approximately 35,000 births are registered each year yet the 50 part-time nurses employed by the Parochial Boards delivered only about 1,300 cases while outside Kingston no provision is made for ante-natal clinics. It is estimated that scarcely more than 25 per cent. of the total deliveries in the Island are handled by qualified attendants.

By way of contrast it is noted that in the Corporate Area where about 5,200 births are recorded annually, about 1,500 are delivered in the Kingston Jubilee Maternity Hospital (in 1937 there were 2,520 admissions to this Hospital, 1,950 live births, 17 maternal deaths and 55 infant deaths), a considerable number by doctors and nurses at the homes of mothers and about 200 in Registered Nursing Homes. The Child Welfare Association recorded 11,640 attendances of sick

babies and 5,339 attendances of other babies at their clinics while the Jubilee Hospital and the Association together recorded 7,487 attendances at ante-natal clinics.

Maternity Wards have been completed at the Port Antonio, Buff Bay, Annotto Bay and Sav-la-Mar hospitals. Parochial Boards are said to be showing increasing interest and a desire to co-operate with the Government in providing Public Health Nurses and Maternity and Child Welfare Services.

School Hygiene—The Corporate Area of Kingston and St. Andrew is the only Local Authority provided with a School Medical Service. In this area the nutritional status of from 20-55 per cent. of the 8,000 children examined is stated to be unsatisfactory. In other Parishes Health Officers carried out preliminary surveys on groups of school children. Among 6,830 children examined the nutritional condition of 41 per cent. was stated to be sub-normal, and defective vision was observed in 15 per cent. *School Dental Clinics* are maintained in eleven parishes.

The Schools Medical Officers found that among 1,103 school-children examined 43 gave Wassermann or Eagle reaction; the Kahn reaction was not carried out on each case, but where this test was applied results were almost identical. There was a definite history of yaws in 13 of the 43 positives, thus reducing the number of possible cases of congenital syphilis to 30.

Public Health Sanitation etc.—A year of steady progress and development is recorded: a staff of 3 Senior Sanitary Inspectors, 2 Dispensers, and 28 Sanitary Inspectors is provided to assist Local Boards of Health in various health measures. *The Malaria Control Officer* contributes a separate Report in which is described the control work carried out in the Island.

With regard to *sewage disposal* it is stated that considerable extensions to the sewerage system of Kingston were carried out: plans were completed for sewerage installation in certain areas and work was started on the erection of a modern Sewage Disposal Plant at Kingston Pen. In other areas, 13,643 new latrines were completed during the year (see this *Bulletin* 1938 Supp. p. 245*). Investigation of *water supplies* showed that only about 30 per cent. of the total population have regular access to public water supplies, the rest of the population being dependent upon unsafe sources (see this *Bulletin* 1938, Supp., p. 246*). During the past two years it is said that marked progress has been made in the direction of improving the several main supplies in quantity and quality. Towards the end of the year work was begun on a new Purification Plant for the Kingston supply and on a plant similar in type for the Stony Hill supply. Construction work was also well advanced for augmenting and purifying supplies to four other towns and plans are being prepared for dealing with supplies to smaller towns and settlements.

Regular inspections of *dairies* and *milk shops* were carried out and steady improvement in the production and handling of milk is reported with an increasing use of pasteurized milk. The Medical Department was much occupied during the year with the problem of *housing* (see this *Bulletin* 1938 Supp. p. 246*) which developed with the establishment of a *Central Housing Authority* with powers under the Slum Clearance Law of 1937. Improvement schemes were sanctioned

by Government for dealing with specific areas and surveys of conditions in certain parishes are also being carried out

Recommendations made (see also this *Bulletin* 1938 Supp pp 246*-247*) include (a) Development of Maternity and Child Welfare Work (b) Provision of District Maternity Services and (c) Provision of Chief Sanitary Inspectors of senior type for sanitary areas

Port Health Work—This continued to be carried out along lines previously described (see this *Bulletin* 1938 Supp p 247*) During the year 1 423 vessels entered Kingston and Port Royal and 109 at the outports One case of *bubonic plague* was landed from a vessel arriving from Brazil no other cases occurred As regards *aerial traffic* no aerodrome for land planes has yet been provided 287 seaplanes arrived during the year

Hospitals Dispensaries etc—The need for increased accommodation at several hospitals (many are 20 to 60 per cent overcrowded) is very acute and can only be met in many cases by additional buildings. Maternity Wards were completed at four hospitals (see *Maternity Work* above) tuberculosis wards were added to two district hospitals and three others are in course of erection a new hospital of 50 beds is to be built at Alexandria a new Tuberculosis Dispensary was completed and a new V D Clinic was opened at Kingston The following summary universally measures the volume of work dealt with at the various hospitals etc. in the Island —

Institution	Beds	In patients			Out patients
		Admitted	Treated	Died	
Public Hospital Kingston	380	8 345	8 685	782	180 479
Victoria Lying in Hospital	100	2 520	2 520	17	3 773
19 District Hospitals	903	—	28 471	1 216	79 658
Mental Hospital	2,089	572	2 640	258	—
Lepers Home	120	23	191	14	—
Tuberculosis Hospital	—	116	—	34	—

Among the *Special Reports* appearing in the Report under review are those relating to (a) The Kingston Public Hospital, (b) The Victoria Jubilee Lying in Hospital (c) The Mental Hospital (d) The Lepers Home (e) The Prisons, (f) Tuberculosis Hospital.

The *Out-door Dispensary Services* continue to meet the steady increasing demand of the public. Five new dispensaries were opened during the year at all centres 221 987 attendances for treatment were recorded.

The *training of nurses* continued to be carried out at the Kingston Public Hospital 69 nurses sat for and passed their final examinations. Ten students trained at the hospital qualified as Dispensers.

Notifications of infectious diseases numbered 2,661 and of these 1,311 were cases of *pulmonary tuberculosis* and 781 *typhoid fever* The principal items of morbidity experience during 1937 are briefly referred to in the notes which follow

Judged by general mortality and hospital figures the incidence of malaria declined markedly during 1937. Total deaths ascribed to this cause in the Island numbered 504. In-patients treated for malaria at the Kingston Public Hospital numbered 693 and 29 died. At the District Hospitals 2,974 in-patients were treated, with 114 deaths and 7,347 out-patients were dealt with, suffering from the same cause. The type of infection is not differentiated in any of the hospital cases, neither is this done in the Laboratory where nearly 5,000 blood films were examined for the presence of malaria parasites and positive findings recorded in 803 cases.

The Malaria Officer contributes a detailed report of the year's work of the Department of Malaria. The general programme of malaria control was again extended, and a more generous provision of funds for permanent control measures was provided.

A marked reduction in the number of cases of enteric fever is reported—781 as compared with 1,278 in the preceding year. Deaths in the Island due to this cause numbered 185. The decrease is more marked in the Corporate Area where there were 166 cases with 48 deaths as against 337 cases and 62 deaths in 1936. A water-borne epidemic occurred in a wide rural area of the Parish of St. Catherine between June and September and gave rise to 73 cases. The river which is the source of supply for the people in this area is heavily polluted. Altogether 130 cases and 7 deaths were notified from the Parish of St. Catherine during the course of the year. At the Kingston Public Hospital 137 cases of enteric fever were treated with 43 deaths, and at the 19 District Hospitals there were 413 in-patient cases with 105 deaths and 22 out-patients. During the year 32,454 anti-typhoid inoculations were given, special attention being devoted to the protection of school-children who provide about 30 per cent. of the cases notified. At the Laboratory agglutination tests were applied to 2,596 samples of blood serum. 662 agglutinated positively with *Bact. typhosum*, 468 gave doubtful and 1,450 negative reactions, 1 was positive with *Bact. paratyphosum A* and 3 *Bact. paratyphosum B*.

Of dysentery 132 cases were notified and of these 83 were amoebic, 4 bacillary and 35 unclassified. The Kingston Public Hospital dealt with 37 amoebic cases, 1 bacillary and 6 were unspecified as to type of infection. For the District Hospitals the corresponding figures were 14, 4 and 9 respectively. Dysentery is not referred to in the text of the Report. Deaths due to diarrhoea and enteritis in the Island as a whole numbered 470.

During the year 1,311 cases and 1,019 deaths due to Pulmonary tuberculosis were recorded. 46 per cent. of the cases notified came from the adjacent parishes of Kingston, St. Andrew and St. Catherine. Although there appears to be a progressive decline in the incidence of the disease, investigations carried out during 1937 showed that a very high proportion of children of school age both in urban and rural areas gave a positive tuberculin reaction. In Kingston and Clarendon schools over 90 per cent. and in a Milk River school 97 per cent. were positive. At the Kingston Tuberculous Dispensary 3,664 new patients were examined and 8,550 attendances of old patients were recorded. Outside the Corporate Area, Health Officers recorded 8,154 attendances at their Clinics.

Special Reports describe in detail work at (a) The Tuberculosis Clinic (b) The Tuberculosis Hospital and (c) The Tuberculosis Wards at the Poor House

Mention has already been made of the newly built T B wards at certain hospitals (see *Hospitals* above). It is said that the building of the Tuberculosis Sanatorium will be put in hand early in 1938 (see this *Bulletin* 1937 Supp p 244*). At the laboratory among 1,919 specimens of sputum examined 449 were positive with *Mycobacterium tuberculosis*.

Pneumonia caused the deaths of 653 persons in Jamaica during 1937

Twenty five cases of *leprosy* were notified at the end of the year there were 245 known lepers in the Island 165 of them being in the Lepers Home. The Medical Officer in charge of the Lepers Home contributes a Report describing the year's work at that institution. The wards are still overcrowded especially on the female side. There were 22 admissions 12 patients were discharged 14 died and at the end of the year there were 165 inmates on the registers. Out of 335 smears etc. examined at the Laboratory 199 were positive with *Mycobacterium leprae*.

Helminthic diseases are not mentioned in the text of the Report except one short reference to the fact that in the Lambs River area of Westmoreland 67 per cent of the population were infected with hookworm and that 6,686 treatments were given to 2,268 persons. At the Kingston Public Hospital 27 in patients were treated for ankylostomiasis, and 19 for other intestinal parasites at the 19 District Hospitals under the title *parasites* 363 in patients and 958 out-patients were treated. Faecal specimens examined at the Laboratory numbered 3,528 and of these 1,312 contained *Ancylostome* 734 *Trichuris*, and 207 *Ascaris* ova.

Venereal Diseases—The following records are supplied of cases dealt with during the year —

Treatment Centre	In patients		Out patients	
	Syphilis	Gonorrhoea	Syphilis	Gonorrhoea
Kingston Public Hospital	416	385	1,154	
19 District Hospitals	2,055	1,160	9,017	3,974
Kingston V D Clinic	—	—	4,391	6,227
Montego Bay V D Clinic	—	—	1,223	1,397
Port Antonio V D Clinic	—	—	707	543

Work at the Montego Bay Clinic began in July and at the Port Antonio Clinic in October 1937. The Kingston Clinic was transferred to the newly constructed building in September. A special report of the year's work at the V D Clinics is included in the Annual Report under review (see also *School Hygiene* above).

The work of the *Yaws Commission* in which the Government and the Rockefeller Foundation co-operated ceased in April and the work was taken over by the Government. Under the new scheme Health Officers survey their areas and collect cases for treatment by Medical Officers of Districts at special centres while two *Mobile Health Units* are maintained for work in heavily infected yaws areas.

The Report contains full accounts of the year's activities in the campaign against yaws the following findings are recorded —

Outside areas of highest endemicity

Population 439,819 active cases found 9,508 or 2.2 per cent.

In areas of high endemicity (in four parishes)

Population 76,635 active cases found 6,802, or 8.0 per cent

A total of 129,745 treatments were given to 30,611 cases throughout the Island

At the Laboratory routine serological examinations for syphilis totalled 30,518 and of these 11,910 gave positive and 1,131 doubtful reactions. Smears microscopically examined for gonococci numbered 8,560 and 5,244 of these gave positive findings

Other diseases — Though nephritis is not mentioned in the text of the Report the disease is a serious cause of mortality for 628 deaths were ascribed to this cause. At the Kingston Public Hospital 71 in patients were treated for nephritis and 8 died. How many cases were dealt with in the District Hospitals it is impossible to state for this title is lost in the group *Diseases of the Genito-Urinary System* this group was responsible for 2,785 in patient cases, 4,780 out-patients, and 151 deaths. Cancer caused the deaths of 387 persons in the Island in patients treated for this cause at all hospitals numbered 399 with 57 deaths. Notified cases of diphtheria numbered 29 of scarlet fever 22, of erysipelas 21 of cerebrospinal meningitis 8 and of chickenpox 332.

Scientific — The work of the Government Laboratory continues to increase and during the year under review 71,701 specimens were examined, exclusive of 18,651 larval examinations. It will be impossible to deal with any further increase in the volume of work without increase of staff. The Report of the Laboratory contributed by Dr K. Leigh EVANS contains a detailed account of the nature of the specimens examined and results recorded. The principal of these have been mentioned in various sections of the preceding summary notes.

The following *Special Reports* are a feature of the Report under review —

(1) *Special Tuberculosis Studies* by Dr E. W. FLAHERTY of the Rockefeller Foundation. These studies comprise (a) a Report of the work done at the Mental Hospital during the year and (b) a Report of the work done at the Stony Hill Industrial School. The results of tuberculin tests, X-ray examinations, vaccinated cases and controls etc. are discussed at considerable length.

(2) *The Treatment of Gonorrhoea with Sulphanilamide* by Dr K. Leigh Evans.

This study discusses the results of sulphanilamide therapy in 295 cases.

Financial — Total expenditure on Medical Department Services during 1937 amounted to £211,236, a sum which represents 8.4 per cent. of the total expenditure of the Colony during the same year

CAYMAN ISLANDS (1937)

The Cayman Islands, three in number namely Grand Cayman Little Cayman and Cayman Brac form a dependency of Jamaica and lie between 79° 83' and 81° 30' W longitude and 19° 16' and 19° 45' N latitude. They have a total area of about 104 square miles.

The Annual Medical Report for 1937 had not been received at the time of going to Press on October 16th 1939 (See also this *Bulletin* 1938 Supp p 251*)

TURKS AND CAICOS ISLANDS (1937)

The Turks and Caicos Islands geographically are a sort of annexe of the Bahamas group but in 1973 were annexed to Jamaica which lies about 450 miles to the south west. They are situated between 21° and 22° N latitude and 71° and 72° 37' W longitude and have an area of about 166 sq miles. The chief island Grand Turk is 6½ miles long 1½ broad.

Vital Statistics—In previous issues of this Supplement attention has been called to the fact that the census figures for 1921 recording a population of 5 612 continue to be used each year and applied for the calculation of annual birth and death rates—the practice still persists.

Registered births numbered 165 and *deaths* 90—the birth and death rates (on the basis of the 1921 population) are said to be 29.4 and 16.0 per 1 000 respectively.

Infant deaths are not given but the infant mortality rate during 1937 was said to be 127.

School Hygiene—Under this heading mention is made of the regular dental inspection of school-children—free treatment was given to 92 children and 61 others were treated at reduced rates. Instruction in hygiene was given by teachers in charge of schools.

Public Health Sanitation etc—The health of the Dependency is reported to have been fair. The Inspector of Nuisances reported the sanitary conditions as satisfactory—no quarantinable diseases were notified and the isolation houses in the Hospital grounds were not in use during the year. With regard to *labour conditions* it is said that though 1937 was a normal salt-producing year the salt season is short and the long periods of unemployment give rise to great hardship to labourers and their families. Supplies of fresh meat vegetables etc. are imported in sufficient quantities but the labouring classes lack the means to purchase such foods (see below *pellagra*). If relief work could be provided for labourers between the salt seasons it would serve to ameliorate existing hardships.

Hospitals etc—A brief statement records the yearly admissions to the Hospital Grand Turk viz 5 cases and one death.

Pellagra was in evidence as usual, mostly among those compelled to exist on a restricted and limited diet—there were two hospital cases with one death. At the Dispensary 35–40 infants were treated for diseases of the digestive tract while cases of *anaemia* and patients with *beriberi* like symptoms etc. directly or indirectly due to dietary

LEEWARD ISLANDS (1937)

deficiency and mostly among children, were among other conditions dealt with.

Skin diseases such as *eczema impetigo* etc., were noticeable among children and young women while among adults muscular and articular *rheumatism* acute and chronic *nephritis* *arteriosclerosis* and *diseases of the digestive tract* were commonly treated. Ten cases of *tuberculosis* are mentioned.

Helmithic diseases—Eight cases of *anchuriasis* and one of *taeniasis* were treated at the Dispensary. Dr R. O'REILLY, Government Medical Officer, observes that "ascaris and oxyuris were in evidence among the school children as usual," and adds that great difficulty is experienced in persuading parents to accept offers of free treatment for their children.

Veneral Diseases—For years the Dispensary has provided free treatment for patients unable to pay. The difficulty has always been to persuade patients to continue treatment to cure. During the year two cases of primary *syphilis* and five of *gonorrhoea* were under treatment.

Leprosy remains much about the same." There are five known cases and no new cases were discovered during the year.

Financial—The various details of expenditure totalling £494 19s. 7d. include £46 13s. 1d. spent on Hospital services, £270 5s. 3d. on Pauper Relief, £35 2s. 6d. on the maintenance of Lepers, £94 18s. 8d. for Lunatics and £48 for the Dental Inspection of school-children.

LEEWARD ISLANDS.

Antigua (1937)

Antigua, with Barbuda and Redonda, forms one of the *Presidencies* of the Leeward Islands. It lies in W longitude 61° 45' and N latitude 17° 6'. Its circumference is about 54 miles and area 108 sq. miles, or about half the size of Middlesex.

Vital Statistics—The Registrar-General supplies the following figures: Estimated Population 34,523; registered births 1,157; birth rate 34.53 per 1,000; registered deaths 689; death rate 20.57 per 1,000; infant deaths (excluding stillbirths) 193; infant mortality rate 171.1 per 1,000 births. [It is not clear how these rates have been calculated. On the basis of the given population the birth and death rates would be 33.5 and 20.2 per 1,000 respectively, and if all registered births were live births the infant mortality rate would be 169.8.]

At the end of the Report deaths are classified by sex in age-groups for each of the six parishes in Antigua and for Barbuda. A total of 710 deaths is given and of these 688 occurred in Antigua (see above).

Maternity and Child Welfare Work is carried out by 25 District Nurses in Antigua, one Midwife at Barbuda and the Superintendent of Midwives who reports that good work continues to be done at the

three Government creches where 7 400 children were dealt with during the year ante-natal and post natal work in all districts increases in volume and importance. Pupil midwives receive instruction at the Holberton Hospital. Dr L. R. WYNTER Medical Officer of Districts A and B reports that syphilis is responsible for a high percentage of infant deaths in these areas.

School Hygiene—The medical inspection of school-children is listed under Special Services but actual references in the body of the Report are fragmentary. Dr Wynter observes that in his territory schools were visited and talks given on the prevention of common diseases while Dr C. E. BAILEY reports that periodic visits were paid to all schools in District D. A widespread epidemic of measles caused the closing of many schools in the early months of the year. The Dental Surgeon states that 23 schools were visited during the year 1 066 children treated and lessons on oral hygiene given at each school.

The health of the boys at the *Training School* is stated to have been remarkably good with improvements in physique and general health. During the year 20 boys received treatment for minor cases of sickness.

Public Health Sanitation etc—Sanitary and health conditions in the City of St. John are described as by no means satisfactory owing in large measure to the lack of a trained Sanitary Inspector. Methods of garbage removal are open to objection the large numbers of domestic animals kept are a menace to the health of the community at large and uncontrolled slum areas are a source of expense and anxiety. Few places from which food is distributed are satisfactory and milk is said to be sold under particularly insanitary conditions. The water supply on the whole is satisfactory and adequate as to quantity but steps need to be taken for the protection of the reservoirs from possible contamination. All these matters are receiving the attention of the City Commissioners. The six Sanitary Inspectors in the country districts continued to carry out their duties efficiently and render weekly reports of their work (see this *Bulletin* 1938 Supp. p. 253*). Dr L. R. HURSON Veterinary Surgeon contributes a short report in which he records that 2,979 animals were slaughtered for food purposes and the carcasses examined and that 303 cows were certified as healthy for the supply of milk.

Hospitals Dispensaries etc—During the year various constructional improvements were carried out at the Holberton Hospital where 969 patients were admitted and 1 058 in-patients treated. 87 died. Once again Dr J. E. WRIGHT calls attention to the fact that a very high percentage of admissions were due to preventable diseases. The *training of nurses* was continued as usual at this institution.

Dispensaries are referred to under the heading of Special Services but how many are established is not stated nor are out patient cases at the Holberton Hospital mentioned. The Medical Officer Districts A and B refers to 6 000 non-paying patients (presumably dispensary cases) in District D where there are 5 dispensaries total attendances numbered 10,803 and in District E having a population of 6,500 cases seen at the surgery of the Medical Officer totalled 3 800.

At the *Prison* 681 cases were dealt with but only 15 prisoners received in-patient treatment and no deaths were recorded. At the

Fewkes Institute (for the aged and infirm ?) 138 persons were admitted, 51 discharged and 67 died

Malaria continues to prove a serious public health problem. Many of the villages are situated on the edge of or in close proximity to swamps, and everywhere roadside trenches and crab-holes provide abundant breeding places for anophelines. Control measures continued to be actively implemented to the limits of available resources but these are insufficient to deal adequately with the problem. Improvement has resulted from the routine inspections each week in all villages by Sanitary Officials who strive to overcome local indifference and ignorance. During the year 3062 cases and 49 deaths were ascribed to malaria. At the Holberton Hospital 41 in-patients were treated and 4 died. 37 of the cases and 3 of the deaths were ascribed to subtertian malaria. In Districts A and B 336 cases were treated and in District D 1,353 cases with 6 deaths, and 1 (non fatal) case of *blackwater fever*. The numbers treated in District E are not given but the disease is described as having been very prevalent and it is stated that the dangerous cerebral type was prevalent. In all areas subtertian infections predominate. At the Laboratory where 1580 blood films were examined 199 were found to contain malaria parasites. These include 163 subtertian infections, 13 quartan and 3 *beneson tertian*. Seventeen contained crescents.

Isolated cases of *enteric fever* were reported from various parts of the Island between August-October but details of cases are not supplied. Possibilities for contamination of certain water supplies were discovered, and steps were immediately taken to remedy defects in this connexion. At the Holberton Hospital 21 cases and 4 deaths were ascribed to this cause. Four cases were reported in District A and five in District E, all were hospitalized and all contacts received T.A.B. inoculation. At the Laboratory the Widal test was applied to 30 samples of serum, and 12 positive reactions recorded. *Dysentery* was limited to sporadic cases. In-patient hospital cases numbered 9 and of these 6 were suffering from the bacillary type of the disease and 3 died. It is believed that many undiscovered cases of the disease occurred during the year.

Tuberculosis (all forms) was responsible for 26 hospital in-patient cases. 15 of these were suffering from the *pulmonary* form of the disease and 10 died. It is also stated that 19 cases of pulmonary tuberculosis with 3 deaths occurred in District D and that in District E where 5 new cases were seen, the disease appears to be increasing. The Laboratory Report observes that out of 87 specimens of sputum examined 22 were positive with *Mycobacterium tuberculosis*.

An epidemic of *measles* occurred in the early part of the year and caused the closing of many schools. The infection appears to have been introduced from St. Kitts during February and to have spread to all Districts. No cases appear in the Returns of the Holberton Hospital and though mention of the epidemic occurs in all District Reports, in only two of them are details supplied. In District A 135 cases were recorded, but it is added that "the figure does not show by any means the numbers of cases". In District D there were 260 cases with 3 deaths. Though only two (non-fatal) cases of *influenza* appear in the Hospital Returns, the disease appears to have had marked incidence. In District A, 654 persons were treated and 2 died, in

District C it was one of the chief causes of illness (no details given) affecting chiefly young and old people and in District D 95 cases were dealt with and 1 death ascribed to this cause.

Leprosy appears to be increasing there are 35 cases in the Lepers Home and 34 known cases outside. Legislative provision has been made for the compulsory segregation of infected persons (see this *Bulletin* 1938 Supp. p. 253*).

Veneral Diseases—The percentage of the population infected with syphilis is said to be very high though precise knowledge concerning this is lacking. gonorrhoea is also the cause of a high morbidity rate. At the Holberton Hospital 68 in patients were treated for syphilis and 10 deaths were attributed to this cause and there were also 34 cases of gonorrhoea and 6 of gonorrhoeal or purulent ophthalmia. In District C 124 cases of syphilis and 50 of gonorrhoea and in District E 150 cases of syphilis were seen. At the Laboratory the Kahn test was applied to 787 samples of sera and 363 positive reactions were recorded. Yaws is mentioned in the District E report where it is said 7 to 10 new cases are seen each year.

With regard to other conditions it is stated that *malnutrition* and improper feeding are the cause of much illness and not a few infant deaths. deficiency disease are not uncommon. *Impetigo* and other skin conditions are frequently met with among children. A large number of children suffer from *ascariasis* in District D alone 804 children were treated for this condition.

Scientific—Under this heading all that can be included is the summary of Laboratory work. During the year 3,367 specimens of various kinds were examined and reported upon. some of the findings recorded are referred to in the preceding notes.

Financial—Total expenditure on Medical Department services 1937 during amounted to £13,971 personal emoluments accounting for £5 035 of this sum.

Dominica (1937)

Dominica the largest and most southerly island of the Leeward Islands Colony is of volcanic origin. It measures about 29 miles long and 15 broad and has a total area of 304 sq miles or about double that of the Isle of Wight. It is situated between 15° 20'–15° 45' N latitude and 61° 13'–61° 30' W longitude and lies 93 miles south of Antigua.

Vital Statistics—No Census has been taken since 1921 but the estimate of the Registrar-General shows the population to number 49,483 (23,466 males, 26,017 females) at the end of 1937. Registered live births numbered 1,487 deaths 711 and stillbirths 62. The birth and death rates were 30.3 and 14.5 per 1,000 of the mid year population respectively.

Of the live births 58 per cent. and of the stillbirths 61 per cent were illegitimate.

Infant deaths numbered 170 giving an infant mortality rate of 114.3 per 1,000 live births.

During recent years the tendency of the birth rate to decline has been accelerated by reason of the emigration of young people to other

Veneral Diseases—District Medical Officers reported 648 cases of syphilis and 346 cases of gonorrhoea and its complications. Fifty two cases of syphilis 47 of gonorrhoea 6 of soft chancre and 4 of lymphogranuloma were treated in Hospitals. Of years 1 108 cases were notified, and 3,853 cases of the disease and its sequelae were treated during 1937. One section of the Windward Coast is said to be especially difficult of control for it is only possible for a Medical Officer to visit the area once a month.

Of the 32 known cases of leprosy in the Island 4 died during the year two new cases were notified both former residents of the Guianas. The construction of a new Leper Home approaches completion.

Other diseases—It is stated that diseases of the digestive system account for a high proportion of the cases seeking treatment, and that many of these are debilitated persons suffering from deficiency of protective foods in their diets. Digestive disturbances among infants due to improper feeding are exceedingly common.

Financial—Actual expenditure on Medical Services during 1937 amounted to £11,204 a sum which represents 17 per cent. of the revenue or 16½ per cent. of the expenditure of the Presidency during the same year.

Montserrat (1937)

Montserrat, named by Columbus after a mountain in Spain, lies in 18°45' N latitude and 61° W longitude 27 miles S W of Antigua. Its length is 11 miles and its greatest breadth 7 miles and its area 32½ sq miles.

Vital Statistics.—The estimated population at the end of the year was 18 712. Registered births numbered 449 and deaths 210 giving crude birth and death rates of 32·7 and 15·3 per 1 000 respectively. Infant deaths numbered 71 with an infant mortality rate of 158·1 per 1 000 live births. (It is presumed the 449 registered births were live births stillbirths numbered 24 and are separately mentioned.)

Maternity and Child Welfare Work—Special attention is paid to ante-natal work. Expectant mothers registered at the Glendon Hospital are advised to attend for examination each month during the latter part of pregnancy a good response resulted. In the Maternity Ward of the Hospital 80 mothers were delivered of their babies there were no maternal deaths. No organized Child Welfare work has so far been attempted though plans are under consideration. Meanwhile a follow-up of babies born in Hospital has been commenced, and mothers have been invited to bring their babies to the Hospital for examination each month.

School Hygiene—Owing to the pressure of other work it is said that some degree of irregularity characterized the usual practice of periodical visits to schools by Medical Officers. The question of overcrowding has in some cases been dealt with by the provision of increased accommodation a new school for infants has also been erected. Special attention was devoted to improving latrine accommodation. The usual instruction in the elements of hygiene was continued.

Public Health Sanitation etc—The first two months of the year were unusually wet and were followed by four months of drought. These unfavourable weather conditions adversely affected the agriculture of

the Island another bad year was experienced and the general economic situation gave rise to great anxiety. nutritional disturbances and general poverty were more in evidence than usual.

The sanitation of the town of Plymouth leaves much to be desired and in country districts conditions are even less satisfactory (see also this *Bulletin* 1938 Supp p 257*). The augmented water supply of Plymouth was satisfactory as to quality and an adequate supply was always available even during the dry periods of the year. consumption steadily increases owing to the increasing number of water borne septic tank installations in private dwellings. In country districts piped supplies have been constructed to some of the remote villages. Steady progress is reported in housing and reconstruction schemes and new buildings are helping to relieve congestion (see this *Bulletin* 1938 Supp p 258*).

The staff of the sanitary department remained unchanged. Sanitary Officers continued to render their quarterly reports of work accomplished and their suggestions for improving conditions. These reports are considered at the meetings of the Board of Health and necessary action taken.

Hospitals Dispensaries etc—The new Glendon Hospital (see this *Bulletin* 1938 Supp p 258*) though formally opened by His Excellency the Governor in February was not ready for the accommodation of patients until the middle of May. The new building provides male and female general wards maternity ward children's ward out patient departments etc. There is bed and cot accommodation for 40 patients. During the year 495 patients were admitted, 511 were treated and 19 died. In addition 315 out patients were dealt with. *Dispensary Clinics* were held at weekly intervals at three centres and monthly visits were resumed to a fourth centre towards the end of the year.

The principal ailments treated at the hospital and dispensaries during the year included the following—

Three cases of *malaria* were reported one fatal subtertian and two benign tertian. Anophelines though present around the swamps near the West Coast have not become widespread throughout the Island or they have remained uninfected. Twelve cases of acute *filariasis* are recorded three being treated as in patients. The offending *Culex fatigans* is common and a campaign has been organized for the extermination of these pests.

Epidemics of *influenza* occurred and the gastro-intestinal form exacted a heavy toll of infant lives while broncho-pneumonia was a frequent complication. Eight deaths were ascribed to influenza and ten to broncho-pneumonia.

No cases of *fevers of the enterica group* were reported. Hospital returns record 2 cases of *amoebic* and 3 of *bacillary dysentery*. In the Island mortality returns one death was ascribed to *dysentery* (unclassified) 39 to *diarrhoea and enteritis* among children under 2 years of age and 5 to persons over two years of age.

Among 18 cases of *tuberculosis* (all forms) reported during the year were 15 of the *pulmonary* form of the disease and of the latter 7 died. *Helminthic diseases*—It is said that about 50 per cent of the population and 75 per cent of the children are infected with round worms.

Veneral Diseases—In the Island as a whole 18 deaths were certified as due to syphilis and more than half of these were cases of congenital syphilis in the first two years of life. Four cases of primary and a considerable number of tertiary manifestations of the disease were seen during the year. Among other venereal diseases treated were 17 cases of acute gonococcal arthritis 9 cases of acute salpingitis and 10 cases of procto-vaginitis in young girls.

It is said that yaws is slowly and steadily disappearing, and that acute primary cases are gradually becoming fewer. Crab yaws and yaws ulcers are still met with and in some cases are very resistant to treatment. Injections given for yaws and syphilis totalled 1,278.

Other diseases—The general mortality returns record 19 deaths due to cardio-vascular diseases and 21 under the title *Sensility* among the latter were 7 centenarians, one a woman aged 109 years. Cancer claimed the lives of 15 persons and nephritis 10.

Financial—Expenditure on Medical and Sanitary Services during 1937 amounted to £3,371 a sum which represents about 10 per cent. of the total revenue of the Presidency during the same year.

St. Christopher and Nevis with Anguilla (1937)

The islands of St. Christopher and Nevis with Anguilla are part of the Lesser Antilles group and constitute one of the five Presidencies forming the Leeward Islands Colony in the West Indies. Their total area is about 150 sq. miles.

Vital Statistics—Among the legislative measures passed during the year mention is made of "An Ordinance to amend the Registration Ordinance 1885" what amendments are to be introduced is not stated. As regards the relevant vital data for 1937 they may be classified as follows—

Item	St. Kitts	Nevis	Anguilla	The Presidency
Estimated population	18 694	13 724	5 639	38 057
Registered Live Births	807	411	193	1 411
Birth Rate	43.2	29.9	34.2	37.1
Registered Deaths	632	183	71	886
Death Rate	33.8	13.3	12.6	23.3
Infant Deaths	169	44	15	228
Infant Mortality Rate	200.0	107.1	77.7	181.6
Stillbirths	60	21	6	77

Maternity and Child Welfare Work—The Baby Saving League managed by a Board of voluntary workers with the Senior Medical Officer as Chairman and the District Matron as Secretary continues to function successfully six crèches are maintained in St. Kitts and one in Nevis, but additional crèches are an urgent requirement. The Medical Officer No. 1 District observes, "The feeding of infants is still a depressing problem and advice usually falls on barren ground."

The Medical Officers of Districts 2, 6 and 7 all comment upon the incidence of congenital syphilis in children—endeavours are made to persuade expectant mothers to submit to a Kahn reaction test but not all are willing to do so, nor are they inclined to act upon medical advice given them.

The record of work carried out in the Maternity Wards of the various Hospitals reads as follows—*Cunningham Hospital* 102 labour cases 3 maternal deaths *Alexandra Hospital* Nevis 68 labour cases *Pogson Hospital* 12 and the *Cottage Hospital* Anguilla 1 labour case.

During the year 27 registered midwives were supervised and supplied with drugs and dressings for their District work—only 14 of these women receive Government pay. Records of the year's work include mention of 428 visits of mothers to midwives 177 visits of midwives to crèches 163 ante natal visits and 119 first visits to infants. Reference is made to the status and training of midwives on the Register and it is pointed out that 18 years ago a large number of midwives were registered by virtue of the fact that they were in actual practice at the time the Midwifery Ordinance was passed. It is added that these women are now old decrepit and dirty and their names should be removed from the Register though if this were done they should be compensated from parochial funds.

School Hygiene—Once again work under this heading is mainly confined to details supplied by the Dental Surgeon Dr E. A. WILKIN (see this *Bulletin* 1938 Supp. p. 259*) who visited the primary schools in the Presidency. Apart from the record of extractions for school-children the Dental Surgeon observes: "The children of the Anguilla schools still seem undernourished and I am satisfied with the marked improvement in the condition of the St. Kitts children. I feel much more could be done to educate the children and parents by way of lectures in the school—not only on the care of the teeth but on general health matters."

Public Health, Sanitation etc—Mosquito control measures continued to be applied throughout the year. Descriptions of methods of *sewage and refuse disposal* remain unchanged (see this *Bulletin* 1938 Supp. p. 260*) and the only new item of information relating to *water supplies* describes an additional source of supply which provides 28 000 gallons per day. The *housing* of the working classes remains a matter demanding urgent attention—considerable congestion is a feature of some districts.

Port Health Work—Though the Port of Basseterre is provided with a Port Health Officer (see this *Bulletin* 1938 Supp. p. 260*) no record of the year's work appears in the Report under review.

Hospitals, Dispensaries etc—Separate reports describing the year's work in each of the medical institutions of the Presidency are included in the Report under review. For the four Hospitals, the relevant details may be classified as follows—

Hospital	Admissions	Treated	Deaths	Out patients
Cunningham, St. Kitts	700	812	71	110
Alexandra, Nevis	620	650	40	89
Pogson	78	84	4	80
Cottage Anguilla	43	—	1	59

At the Cunningham Hospital, St. Kitts, and the Alexandra Hospital, Nevis, provision is made for the *training of nurses*.

To the *Home for the Infirm Poor* St. Kitts, 55 persons were admitted and during the year 113 persons were accommodated. 9 of the inmates were admitted to Hospital and 39 deaths were recorded.

The principal diseases treated during the year and commented upon in the Report under review include the following —

Malaria —It is again stated that anopheline mosquitoes are present in Nevis but do not appear to spread to St. Kitts or Anguilla. During the year 78 cases of malaria with 1 death were reported. Only 2 non-fatal cases were treated at the Cunningham Hospital St. Kitts but it is noted in addition that there were 32 cases of *unspecified fever* with 1 death. At the Alexandra Hospital Nevis, 22 (non-fatal) cases of the disease were dealt with. District Medical Officers make no mention of the incidence of malaria in their respective areas. The Report of the Bacteriological Laboratory refers to the examination of blood films but no findings are recorded.

Of *filariasis* 317 cases were notified and 4 deaths were ascribed to this cause. The Medical Officer No. 4 District reports the disease as "fairly common" in his district.

Influenza gave rise to 557 cases and was the cause of 3 deaths. 128 cases of *measles* were reported. No case of *smallpox* is recorded, but during the year 794 vaccinations were carried out.

A considerable decline in the incidence of *enteric fever* is noted, only 72 cases being notified as compared with 250 in the preceding year. It is said that 4 deaths were ascribed to the disease but the Cunningham Hospital Returns show that among 21 in-patients treated, 5 deaths occurred. Attention is called to the fact that District Medical Officers fail to make full use of the Laboratory services available: in only 6 out of the 72 cases of enteric fever were specimens of blood submitted for serological diagnosis. Of these 6 specimens 5 agglutinated *Bact. typhosum* and 1 *Bact. paratyphosum A*. *Dysentery* was responsible for 139 cases and 4 deaths but in six out of the seven Reports of District Officers the incidence of *enteritis* is commented upon. In District No. 3 alone out of 278 cases recorded with 12 deaths, 177 of the cases and all the deaths occurred among children under two years of age. The fly nuisance is held to be mainly responsible for the disease which is also referred to as *summer* or *fly diarrhoea*.

Tuberculosis is responsible for 38 per cent. of the total deaths due to all causes in the Presidency and returns the highest mortality rate for any individual disease. During the year 148 cases with 61 deaths were notified. Greater facilities for the treatment of the disease are an urgent necessity and it is suggested that the unroofed Quarantine Station (see this *Bulletin* 1933 Supp. p. 260*) would provide a reasonable anti-tuberculosis centre. *Pneumonia* which is the second most serious cause of mortality gave rise to 83 cases and 45 deaths.

Helminthiasis —It is said that infection with *ascaris* appears to be the rule rather than the exception amongst children of the lower classes. The majority of the District Medical Officers comment upon the high incidence of round-worm infestation among children, while the Medical Officer No. 4 District also observes that the residents in one area are heavily infected with *ankylostomiasis*.

Of leprosy 19 cases and 8 deaths were reported. The usual report on the work at the Leper Home is contributed by Dr G D McLEAN the following details are supplied —

Sex	Admitted	Treated	Died	Discharged	Remain
Male	2	32	5	2	25
Female	2	19	3	—	16
Totals	4	51	8	2	41

In addition 22 *extern lepers* were regularly visited and treated at their homes.

Veneral Diseases —Recorded cases of *syphilis* numbered 878 and 39 deaths were ascribed to the disease. 743 cases of *gonorrhoea* were also reported. The Report observes that there are good reasons for believing that these figures do not represent the true incidence of venereal diseases in the Presidency. The majority of District Medical Officers comment upon the incidence of these diseases in their respective areas and especially of the incidence of congenital *syphilis* in young children (see also *Maternity and Child Welfare Work* above). The Medical Officer No 4 District reports ten cases of *climatic bubo* and 2 of *granuloma venereum* in the District and says that *gonorrhoea* and *syphilis* are especially evident at the time of the return of the schooners from San Domingo with their complement of labourers who have been working on the sugar estates adding that contact with the Republic (of San Domingo) has certainly been responsible to a great extent for the incidence of venereal diseases here. During the year 1 208 cases of *jaund* were dealt with.

At the Bacteriological Laboratory where the Kahn test is the serological standard adopted for the diagnosis of *syphilis* 363 such tests were carried out. 122 gave positive and 21 doubtful reactions. It is noted that the Medical Officers of Districts 2 and 6 submitted no less than 320 of the specimens for examination.

Other Diseases —The classified Returns of the Cunningham Hospital show 29 cases of *cancer* with 5 deaths. the Medical Officer No 2 District states that *carcinoma* is definitely on the increase among all classes and races of the population and that cases of *carcinoma* of the tongue breast uterus and bladder were seen during the year. *Ulcers* are common. the Medical Officer No 7 District estimates that 25 per cent of the school-children in that area suffer from *ulcers*. At the Cunningham Hospital 36 in-patients were treated for the condition at the Alexandra Hospital 23 at the Pogson Hospital 8 and at the Cottage Hospital 3 (see also this *Bulletin* 1938 Supp p 262*).

Scientific —At the Bacteriological Laboratory 544 specimens were examined and reported upon. The 363 Kahn and 6 Widal tests have already been mentioned under the headings of *venereal diseases* and *enteric fever* respectively. No other findings are recorded in the section entitled Report of the Bacteriological Laboratory. The Medical Officer No 8 District sent among other specimens 3 of human sputum one of which proved to be positive with *Mycobacterium tuberculosis*.

At the Cunningham Hospital, St. Kitts and the Alexandra Hospital, Nevis, provision is made for the training of nurses.

To the Home for the Infirm Poor, St. Kitts, 55 persons were admitted and during the year 113 persons were accommodated. 9 of the inmates were admitted to Hospital and 39 deaths were recorded.

The principal diseases treated during the year and commented upon in the Report under review include the following —

Malaria — It is again stated that anopheline mosquitoes are present in Nevis but do not appear to spread to St. Kitts or Anguilla. During the year 78 cases of malaria with 1 death were reported. Only 2 non-fatal cases were treated at the Cunningham Hospital, St. Kitts, but it is noted in addition that there were 32 cases of unspecified fever with 1 death. At the Alexandra Hospital, Nevis, 22 (non-fatal) cases of the disease were dealt with. District Medical Officers make no mention of the incidence of malaria in their respective areas. The Report of the Bacteriological Laboratory refers to the examination of blood films but no findings are recorded.

Of falciparum 317 cases were notified and 4 deaths were ascribed to this cause. The Medical Officer, No. 4 District reports the disease as fairly common in his district.

Influenza gave rise to 557 cases and was the cause of 3 deaths. 128 cases of measles were reported. No case of smallpox is recorded, but during the year 794 vaccinations were carried out.

A considerable decline in the incidence of enteric fever is noted, only 72 cases being notified as compared with 250 in the preceding year. It is said that 4 deaths were ascribed to the disease but the Cunningham Hospital Returns show that among 21 in-patients treated, 5 deaths occurred. Attention is called to the fact that District Medical Officers fail to make full use of the Laboratory services available. In only 6 out of the 72 cases of enteric fever were specimens of blood submitted for serological diagnosis. Of these 6 specimens 5 agglutinated *Bact. typhosum* and 1 *Bact. paratyphosum A*. *Dysentery* was responsible for 139 cases and 4 deaths, but in six out of the seven Reports of District Officers the incidence of *enteritis* is commented upon. In District No. 3 alone out of 278 cases recorded with 12 deaths, 177 of the cases and all the deaths occurred among children under two years of age. The fly nuisance is held to be mainly responsible for the disease which is also referred to as "summer" or "fly" diarrhoea.

Tuberculosis is responsible for 38 per cent. of the total deaths due to all causes in the Presidency and returns the highest mortality rate for any individual disease. During the year 148 cases with 61 deaths were notified. Greater facilities for the treatment of the disease are an urgent necessity and it is suggested that the unused Quarantine Station (see this Bulletin 1938 Supp. p. 260*) would provide a reasonable anti-tuberculosis centre. *Pneumonia* which is the second most serious cause of mortality gave rise to 83 cases and 45 deaths.

Helminthiasis — It is said that infection with *ascaris* appears to be the rule rather than the exception amongst children of the lower classes. The majority of the District Medical Officers comment upon the high incidence of round worm infestation among children, while the Medical Officer, No. 4 District also observes that the residents in one area are heavily infected with *ankylostomiasis*.

Of leprosy 19 cases and 8 deaths were reported. The usual report on the work at the Lepar Home is contributed by Dr G. D. McLEAN, the following details are supplied —

Sex	Admitted	Treated	Died	Discharged	Remain
Male	2	32	5	2	25
Female	2	19	3	—	16
Totals	4	51	8	2	41

In addition 22 *extern leprosi* were regularly visited and treated at their homes.

Veneral Diseases — Recorded cases of syphilis numbered 978 and 39 deaths were ascribed to the disease. 743 cases of gonorrhoea were also reported. The Report observes that are good reasons for believing that these figures do not represent the true incidence of venereal diseases in the Presidency. The majority of District Medical Officers comment upon the incidence of these diseases in their respective areas and especially of the incidence of congenital syphilis in young children (see also *Maternity and Child Welfare* Work above). The Medical Officer No. 4 District reports ten cases of *cinchona* and 2 of *granuloma venereum* in the District and says that gonorrhoea and syphilis are especially evident at the time of the return of the schooners from San Domingo with their complement of labourers who have been working on the sugar estates adding that contact with the Republic (of San Domingo) has certainly been responsible to a great extent for the incidence of venereal diseases here. During the year 1,208 cases of yaws were dealt with.

At the Bacteriological Laboratory where the Kahn test is the serological standard adopted for the diagnosis of syphilis 363 such tests were carried out. 122 gave positive and 21 doubtful reactions. It is noted that the Medical Officers of Districts 2 and 6 submitted no less than 320 of the specimens for examination.

Other Diseases — The classified Returns of the Cunningham Hospital, show 29 cases of cancer with 5 deaths. The Medical Officer No. 2 District states that carcinoma is definitely on the increase among all classes and races of the population and that cases of carcinoma of the tongue, breast, uterus and bladder were seen during the year. *Ulcers* are common. The Medical Officer No. 7 District estimates that 25 per cent of the school-children in that area suffer from ulcers. At the Cunningham Hospital, 36 in-patients were treated for the condition, at the Alexandra Hospital 23, at the Pogson Hospital 8 and at the Cottage Hospital 3 (see also this *Bulletin* 1938 Supp., p. 262*).

Scientific — At the Bacteriological Laboratory 544 specimens were examined and reported upon. The 363 Kahn and 6 Widal tests have already been mentioned under the headings of venereal diseases and enteric fever respectively. No other findings are recorded in the section entitled Report of the Bacteriological Laboratory. The Medical Officer No. 6 District sent among other specimens 3 of human sputum, one of which proved to be positive with *Mycobacterium tuberculosis*.

Excellent work is carried out by the District Nurses who are all trained midwives with a knowledge of the proper care and management of newly born infants. They attend confinements in the rural districts and advise mothers as to the proper care and upbringing of their babies.

The Baby Welfare League continued to function with success but its scope and usefulness is greatly restricted owing to lack of funds. *The Child Welfare Clinic* continued to be held weekly at the Colony Hospital, St. George (see this *Bulletin* 1938 Supp. p. 264*). It is noted that during 1937 diseases of early infancy were responsible for 150 deaths and of these 126 were ascribed to *marasmus*. Parental ignorance and neglect, plus the high percentage of illegitimate births are the principal causative factors.

School Hygiene—In seven of the eight Districts 18 498 school children were medically examined during the year. Among 4 783 children showing defects of one kind or another 1 440 required treatment for *intestinal parasites* 1 087 for *dental defects* 871 for *skin affections* 542 showed *enlarged tonsils* 387 were affected with *scabies* 137 with *yaws* and 124 were suffering from *malaria*. The children are examined at four monthly intervals throughout the year in order to continue this work with maximum efficiency the appointment of a full time School Medical Officer is again recommended (see this *Bulletin* 1938 Supp. p. 265). School-children suffering from dental defects receive free treatment at the *Dental Clinic* at the Colony Hospital during the year under review 772 children were dealt with. Elementary hygiene is taught in all schools and during the usual *Annual Health Week* lectures were given by members of the Education and Medical Departments on suitable health subjects.

Public Health Sanitation etc—The year under review was marked by an unusually long dry season. The Colony was free from such major infections as smallpox, plague, etc. but a few cases of poliomyelitis were notified, while a widespread epidemic of whooping cough with some severe cases was recorded. Sanitary Inspectors continued their routine *anti-malarial* control duties, the work being considerably extended in the remote rural districts in an effort to teach the people how to reduce the incidence of mosquitoes in their areas.

With regard to *sewage disposal* work was commenced on the installation of a water borne system in the town of St. George and considerable progress with this work is reported. The poorer houses in rural areas have no latrine accommodation whatsoever and steps are being taken with a view to introducing the bored hole type of latrine in sufficient numbers to meet the needs of the rural population throughout the Island. In the larger towns *refuse* is disposed of by incineration and it is hoped that similar methods of disposal will be adopted in the smaller townships. No further *water supplies* were installed, but it is hoped that piped-supplies can be extended to districts as funds permit. In the Island of Carriacou water shortage sometimes assumes serious proportions until the arrival of the heavy rains in October.

A commission was appointed to enquire into the economic and living conditions of the *labouring classes* and a memorandum on the economic condition of labourers was submitted to Government by the Senior Medical Officer. In the towns the District Boards are responsible for

housing and town planning but in the rural areas where housing conditions are far from satisfactory there appears to be no controlling authority. These matters are receiving careful consideration with a view to steps being taken to effect improvements.

The control of *food supplies* continued to be exercised especially in regard to milk and milk vendors. The new slaughter house meat and fish markets were formally opened and brought into use during the year. The staff of Sanitary Inspectors continued to carry out their varied routine duties and a detailed record of the year's work is supplied. The post of Chief Sanitary Inspector is still unfilled and this vacancy to some extent diminishes the efficiency of the work for which the staff is responsible.

The training of Sanitary personnel was carried on as opportunity occurred. Four Inspectors sat for the examination of the Royal Sanitary Institute but results were not to hand prior to the issue of the Annual Report.

Port Health Work—No diseases under the Quarantine Regulations gained entry to the Colony during the year. Vaccination of passengers surveillance and disinfection of baggage were carried out when deemed necessary.

Hospitals Dispensaries etc—There are 3 *General Hospitals* 7 *Dispensaries* and 18 *Medical Visiting Stations* in the Colony. The Medical Visiting Stations are staffed by a resident nurse who is also a trained midwife and are visited at least once each week by the Medical Officer of the District. These nurses treat minor ailments and injuries attend confinements assist Medical Officers with the sick in the medical inspection of school-children and the giving of injections etc. At these Visiting Stations 643 confinements were attended 1 027 infants visited in their homes and 1 453 general nursing cases dealt with during the year. Attendances at the various hospitals dispensaries and visiting stations for treatment numbered 16 697. The record of work dealt with at hospitals and other institutions is given below—

Institution	Admitted	Treated	Died
Colony Hospital	2 058	2 120	82
St. Andrews Hospital	375	382	5
Carnacou	232	245	10
Mental	48	202	8
Tuberculosis	44	57	41
House of Refuge	—	171	22
Prison Infirmary	40	40	—
Lepet Settlement	—	14	—

The training of probationer nurses was continued by the Resident Surgeon Matron and Senior Sisters at the Colony Hospital.

Recorded cases of *malaria* numbered 9 411 with 83 deaths. These figures are the lowest noted during the past three years. Incidence is less in all but two districts and the decline is attributed to the success of anti malarial work undertaken. At the Colony Hospital 85 in-patients were treated with 4 deaths at St. Andrew's Hospital 3 with 1 death and at Carnacou Hospital 497 with 6 deaths with the

exception of 5 subtertian cases in the Colony Hospital, types of infection were not differentiated.

No case of *smallpox* has been recorded for many years, but the population is adequately protected by compulsory vaccination regularly carried out.

There was a marked decrease in the number of cases of *enteric fever* and for the first time for many years no case was recorded in the town of St George nor in District V nor for the second consecutive year in District IV. Altogether 19 cases with 9 deaths were reported, all were treated as hospital in patients, and in addition 372 contacts received T.A.B. inoculation. *Dysentery* is a notifiable disease and during the year 36 cases with 1 death were notified. In the Island of Carriacou the long dry season followed by torrential rains, by washing the soil into collecting tanks and drinking ponds brought about a severe outbreak of *dysentery and enteritis*. Of the 36 cases of dysentery recorded 31 occurred in Carriacou, and in the Colony as a whole 2 195 cases of *diarrhoea and enteritis* with 145 deaths were recorded.

During the year 79 cases of *pulmonary tuberculosis* were notified, but 83 deaths were ascribed to this cause. Forty four patients were admitted to the new Tuberculosis Hospital, where 57 patients were treated and 41 died. The disease appears to have increased steadily in recent years. Examination of all contacts is to be undertaken and it is hoped that by this means cases will be detected in the early curable stages so that in time incidence will be reduced.

The prevalent *helminthic diseases* throughout the Colony are *ascariasis* and *ankylostomiasis* but the latter infestation does not occur among the natives of the Island of Carriacou. This freedom from the disease in Carriacou is ascribed to lighter rainfall and different type of soil. Definite action to improve rural sanitation is under consideration, meanwhile educational campaigns aim at the instruction of the people in sanitary measures directed to the eradication of helminthic infestations. The following Table sets out the 1937 experience in connexion with these diseases —

Parish	Medical District	Ascariasis	Ankylostomiasis
St George	I	Cases 1,520	Cases 1,057
St John	II	1,467	418
St Mark	III	6,328	299
St Patrick	IV	1,387	40
St Andrew	V	4,272	1 724
	VI	3,269	153
St David	VII	1,657	543
Carriacou	VIII	1,514	11†
Totals		20 414	4,287

† All imported

Two new cases of *Leprosy* were reported. There were 14 patients in the Leper Settlement 11 of whom were males (see this *Bulletin* 1938, Supp. p 267*)

Veneral Diseases—Cases of syphilis treated during the year numbered 772 a sharp increase of 249 cases over the 1936 record 48 deaths were ascribed to this cause. For gonorrhoea 1 122 persons were under treatment 18 being treated as hospital in patients. This condition also shows increased incidence by comparison with 1936 experience. It is stated that venereal diseases are increasing owing to the ineffectiveness of present methods of treatment and that to deal adequately with the problem a Venereal Diseases Clinic should be established. An increase is also recorded in the incidence of yaws for 2,142 cases were treated as against 1,399 in the preceding year. District Medical Officers are of the opinion that recent cases of the disease are responding less satisfactorily to N A B and that possibly a resistant strain of *S. pertenues* is being encountered. Treatment with other arsenicals is to be tried out.

Other diseases—The report under review mentions a long continued and widespread epidemic of whooping cough with some severe cases that mumps was also moderately prevalent and that influenza with and without bronchial symptoms was fairly prevalent. Hospital returns mention 8 non fatal cases of whooping cough none of mumps and one case of influenza but there were 82 in patient cases of bronchitis with 5 deaths and 34 of pneumonia with 10 deaths but in the Colony as a whole these two titles were responsible for 37 and 47 deaths respectively.

Cancer and other malignant tumours caused the deaths of 39 persons in 1937.

Financial—Total expenditure on Medical and Sanitary Services during 1937 amounted to £23 792 a sum representing 13·4 per cent of the total revenue of the Colony during the same year.

St. Lucia (1937)

The Colony of St. Lucia is the largest and most northerly of the Windward Islands in the Lesser Antilles group West Indies. It is 27 miles long and 14 miles broad, and has an area of 238 sq miles or slightly larger than the Isle of Man.

Vital Statistics—The relevant facts read as follows —

Estimated Population	Registered Births	Birth Rate	Registered Deaths	Death Rate	Infant Deaths	Infant Mortality Rate
67 404	2,216	32·9	999	14·4	224	101·1

There was a further decline in the death rate but a slight increase in the infant mortality rate by comparison with 1936 experience.

Maternity and Child Welfare Work—The Maternity and Child Welfare Centre in Castries is reported to have performed valuable work throughout the year the work continued to be administered as previously described (see this *Bulletin* 1938 Supp p 267*). Dr H P S GILLETTE Medical Officer No 1 District, applauds the work of the Centre and observes that incorrect infant feeding is a common

contributory cause of infant mortality. In rural areas the Government Nurse and Midwife in each village attends to maternity and child welfare work. It is the intention of Government to extend these services. No details are supplied of the work at the Centre in Castries nor of the work carried out in rural areas but the Obstetric Returns of the Victoria Hospital record 709 cases dealt with in the Maternity Ward, 819 deliveries 6 maternal and 13 infant deaths.

School Hygiene—School premises were regularly inspected by Government Medical Officers and Sanitary Inspectors. School Managers are allowed a small Government subsidy to assist in maintaining in a sanitary condition the latrines at schools under their control. The Medical Officer No 2 District Dr J le V BRISTOL observes that dietary deficiencies are reflected in the condition of the school-children in his District. Free dental treatment for children under 12 years of age is available at the Victoria Hospital. Steps have been taken to extend this service to three other districts.

Public Health Sanitation etc—Throughout the Colony the general health of the population remained satisfactory during the year. The usual routine anti-malarial measures continued to be carried out. These are described in detail by the Chief Sanitary Inspector in his Annual Report which is presented as an Appendix to the Report under review. Methods of *sewage disposal* remain unchanged (see this Bulletin 1936 Supp. p. 253*). In Castries and near villages the arrangements though primitive are effective but in the rural areas where few dwellings possess a latrine of any description conditions are very unsatisfactory. There is no central pipe-borne water supply in the Colony: each town or village has its own small plant and in some cases these are unsatisfactory. A survey of the most dangerous of them was carried out during the year by the Colonial Engineer and the Senior Medical Officer and recommendations for improvements were submitted to Government. With a near prospect of augmenting the water supply in Castries it is hoped that the installation of a water-carriage system for the disposal of excreta will be possible. The only other reference of any consequence to *water supplies* is contained in the Report of Dr M A BYER No 5 District. Dr Byer states that the village of Dennery had a constant supply of very good water throughout the year and adds that the Dennery Water Authority is taking steps to enclose the whole area of the Water Works and so ensure adequate protection of supplies. *Housing* conditions in Castries are not altogether satisfactory. Model cottages built from funds supplied from the Colonial Development Fund are let to persons of the labouring classes at low rentals. Housing in the rural areas is described as "deplorable". So far as the chief *Sugar Estates* are concerned, great improvement in housing and sanitation is reported. Excellent houses of concrete have been built with adequate and well constructed sanitary arrangements and at Roseau a pipe-borne water supply has been installed for the use of the labourers.

Dietary deficiencies are commented upon by most of the District Medical Officers. Government has appointed a Standing Committee to investigate the position with regard to nutrition and take steps to bring about improvement. Numerous small *dairies* exist round Castries and milk supplies are frequently taken and examined. Meat and milk do not commonly figure in the diets of the people at large.

The Senior Sanitary Inspector contributes his usual detailed report of the work of his Department (see this *Bulletin* 1938 Supp p 263*)

Port Health Work—Forty five ships the majority of them from South American ports entered Castries port during the year and were given pratique. No quarantine restrictions were recorded nor was any case of quarantinable disease reported.

Hospitals Dispensaries etc—Various improvements to the building and equipment of the Victoria Hospital were carried out during the year. In patients numbered 2 693 and 113 died. In their separate Reports District Medical Officers frequently refer to the number of out patients treated in their areas but the only established dispensaries mentioned seem to be the Castries Dispensary where 4 889 cases were seen during 1937 and three dispensaries in No 5 Medical District where 7 682 cases were dealt with. The notes which follow summarize the principal reference to morbid conditions dealt with during the year.

Malaria continued to be prevalent especially in areas near marine swamps. *A. tarsimaculatus* is the carrier in the Colony and breeds freely in brackish water until the percentage of sea water reaches 70. A fresh water breeder *A. argyritarsis* is also found but so far it has not been proved that this mosquito is a carrier of malaria (see this *Bulletin* 1936 Supp p 254* and 1937 Supp p 263*). In patient cases numbered 84 with 7 deaths. 3 of the cases were *benign tertian* infections 3 were *quartan* and 78 were unclassified. (The Laboratory Report shows that among 117 blood films examined 31.6 per cent contained *subtertian* parasites 2.5 per cent *benign tertian* and 2.5 *quartan*.) Cases treated at all dispensaries totalled 8 527 the majority of them (4 235) in District 4 and only 408 in District 1 (Castries). The incidence of the disease in District 4 is described as having assumed alarming proportions.

Of *enteric fever* 37 cases were notified—all were sporadic occurring in various parts of the Colony (see *water supplies* above). It is stated that all contacts were inoculated with T.A.B vaccine and in every case the patient was removed to Hospital. Hospital Returns show only 33 cases of which 30 were typhoid with 10 deaths and 3 were non fatal cases of paratyphoid. At the Laboratory 3 specimens of blood serum were submitted to the Widal reaction test but results are not recorded.

No cases of *amoebic dysentery* have been reported for the past two years. No exact figures of the incidence of *bacillary dysentery* are available though it is stated undoubtedly there were some cases during the year.

Forty three cases of *pulmonary tuberculosis* were notified—the disease would appear to be more prevalent than statistics suggest for many cases are believed to pass unrecognized because of ignorance of the people and lack of adequate organization to combat the scourge. District Medical Officers comment upon poor housing conditions and overcrowding. At the Laboratory where 10 specimens of sputum were examined 1 was positive with *Mycobacterium tuberculosis*. The high incidence of *other respiratory diseases* is mentioned *bronchitis* was responsible for the deaths of 55 persons during the year.

Helminthic Diseases.—During the year 7 763 patients were treated for various helminthic infections these cases were diagnosed

clinically so the accuracy of the data is open to question. *Hookworm* is said to be "widespread through the Colony. The damage caused by this disease is not as great as was formerly believed for laboratory diagnoses have shown that many cases of *anaemia* and debility formerly ascribed to hookworm, have been proved to be due to malaria. *Round-worm* infestations are common in all members of the labouring classes.

Four cases of *leprosy* were admitted to the Leper Asylum 6 patients died and at the end of the year there were 25 inmates.

Veneral Diseases—From the five Districts 1 031 cases of *syphilis* were reported and at the V.D. Clinic in Castries 247 cases were seen and treated of *gonorrhoea* 1 834 cases were reported from the Districts and 98 cases were dealt with at the V.D. Clinic. At the Victoria Hospital 57 in-patients were treated for *syphilis* 15 for *gonorrhoea* and 38 for other venereal diseases.

Cases of *yaws* reported during the year numbered 508. Treatment along intensive lines was continued the disease appears to be declining steadily and the belief is expressed that shortly *yaws* will cease to exist in the Colony.

Other diseases commented upon in the Report under review include the following. *Nutritional diseases* were responsible for 57 deaths, and *diarrhoea and enteritis* for 53 deaths in the Colony as a whole. *Ulcers and skin diseases* are common.

Scientific—At the Laboratory 1 225 specimens of various kinds were examined. Some of these have been quoted in the preceding notes as regards the remainder no findings are recorded.

Financial—Total expenditure on Medical Department services during 1937 amounted to £10,993 as compared with approved Estimates of £11,208.

St. Vincent (1937)

The West Indian Colony of St. Vincent includes the Island of St. Vincent, the second largest of the Windward Islands, and five of the Lesser Grenadines a chain of islands lying between Grenada and St. Vincent. The island of St. Vincent is 18 miles long and 11 miles broad and has an area of 133 sq. miles, or nearly that of the Isle of Wight the total area of the five smaller islands is some 17.3 sq. miles.

Vital Statistics—The estimated population at the end of the year was 57,526. *Registered births* numbered 2,317 and *deaths* 878 the resulting crude birth and death rates being 40.3 and 15.3 per 1 000 respectively. *Infant deaths* numbered 273 giving an infant mortality rate of 117.8 per 1 000 live births. There were 89 *stillbirths*. Vital facts are summarized in an admirable series of Tables in the Report under review. In a Table presenting the principal causes of death during 1937 it is observed that *sexility* was the certified cause of 99 deaths, *mucosus* 69 *congenital debility* 61 and *ascorbiy* 54. The number of deaths ascribed to the latter cause is exceptionally high.

Maternity and Child Welfare Work—At the Colonial Hospital, Kingstown, 398 labour cases were dealt with of these 339 were normal confinements with 352 babies born alive. Six maternal deaths were recorded. At the Georgetown Hospital, there were 2 normal labour cases and at the Chateaubelair Hospital 8. There are 11 District

Nurse Midwives in the Colony during the year this staff saw 642 expectant mothers attended 261 midwifery cases and paid 10 778 visits to the homes of patients. At the *Ante Natal Clinic* at the Colonial Hospital 92 women attended for advice and treatment.

The *Child Welfare Clinic* continued to function successfully with the Matron of the Colonial Hospital in charge. A nurse qualified in general nursing was appointed to assist and will first undergo a special course of training. New cases registered numbered 132 and attendances recorded totalled 449 during the year.

Four *pupil midwives* trained in the Maternity Ward of the Colonial Hospital, Kingstown passed the Midwives examination.

School Hygiene—There are 37 primary schools in the Colony with 10 223 pupils on the registers. During the year 36 of the schools were visited by District Medical Officers and 5 424 children were medically examined when 14.8 per cent showed dental defects, 6.3 per cent skin diseases (other than scabs), 2.4 per cent signs of anaemia and malnutrition and 1.1 per cent were suffering from vawa (see this *Bulletin* 1938 Supp. pp. 270*-271*). Investigations into conditions of malnutrition among school-children were commenced in co-operation with the Department of Education.

A *Dental Clinic* was inaugurated in April 1937 to provide free dental treatment for school-children and for persons who cannot afford to pay. Between April and the end of the year 1 156 patients had received treatment, 414 of them being school-children.

Public Health Sanitation, etc.—The Report observes that on the whole the state of public health during the year under review was well maintained throughout the Colony. Routine *anti malarial measures* continued to be carried out regularly throughout the Colony. Progress is reported in improving conditions concerned with *sewage disposal*. The inadequacy of *water supplies* is again a subject of comment (see this *Bulletin* 1938 Supp. p. 271*). In Kingstown with its increasing population making a more liberal use of water for sanitary and domestic purposes the situation becomes urgent. On the Leeward Coast villages continue to draw their supplies from springs which during the dry months yield very little water. *Housing* conditions of the wage-earning population are not satisfactory; houses are small and overcrowding is fairly general. Rentals of Government built cottages at Chateaubelair were reduced to bring them within the reach of the lowest paid labourers. Though the majority of proprietors of *estates* have discontinued the erection of houses for their labourers, the Orange Hill group of estates continues to provide unusually good housing for their employees. Good houses of the cottage type suitable for occupation by persons of the peasant class are available in the various Land Settlement areas in the Colony. Services concerned with the sanitary control of articles of food and drink were continued. Details of this work are set out in a series of tabulated statements (see this *Bulletin* 1938 Supp. p. 271*).

A course of lectures and demonstrations covering a period of 15 weeks was given primarily for persons desirous of qualifying as *Sanitary Inspectors*.

Port Health Work—No ports were quarantined during the year. Owing to an outbreak of *acute poliomyelitis* in a neighbouring Colony passengers arriving from that territory were medically examined.

before being allowed to land 49 vessels were boarded and 501 passengers examined. Arrivals at and departures from Kingstown were 2,847 and 3,217 respectively.

Hospitals Dispensaries etc.—The Union Island Hospital (4 beds) which also serves Canouan and Mayreau, was opened in February 1937. In May 1937 patients were transferred from the Old Mental Hospital at the Fort to the new Mental Hospital at Calliaqua. The following Table summarizes the volume of work dealt with during the year at various Government Institutions—

Institution	In-patients Treated	Hospital Deaths	Out patients
Colonial Hospital, Kingstown	1,568	101	Attendances 6,867
Georgetown Hospital	66	3	?
Chateaubelair	134	3	?
Union Island	43	4	?
Tuber House Sanatorium	13	2	?
Mental Hospital	96	6	?
Pauper Asylum	79	13	?
Lepet Settlement	17	1	?

At the 13 *Dispensaries* and 51 *Out-patient Stations* in the Colony 62,781 attendances for treatment were recorded.

The training of nurses was continued at the Colonial Hospital, Kingstown and two probationers passed the qualifying examination (see this Bulletin 1938, Supp. p. 272*).

The notes which follow briefly refer to the principal items of morbidity experience mentioned in the Report under review.

A further decline in the incidence of *malaria* is observed. 376 cases were notified, the lowest recorded experience during the past five years. As in previous years District 2, South, was responsible for the highest proportion of notified cases 42 per cent. of the total recorded. In the Colony as a whole 8 deaths were ascribed to this cause. Only 13 in-patient cases appear to have been dealt with—these were all *benign tertian* infections and treated at the Colonial Hospital, Kingstown. At the newly established Bacteriological Laboratory 51 blood films were examined for the presence of *malaria* parasites—all gave negative findings.

Of *enteric fevers* 25 cases and 8 deaths are said to have been notified, but the classified returns show that 26 cases of typhoid with 8 deaths and one case of paratyphoid A were treated at the Kingstown Hospital, and one case of typhoid at the Georgetown Hospital. The age-group 10-20 provided the greatest number of cases. Only one case of *dysentery* (type not specified) was notified during the year yet two patients suffering from *amoebic dysentery* were admitted to the Kingstown Hospital. Among 40 faecal specimens examined at the Bacteriological Laboratory 3 were positive with cysts of *E. histolytica*. In all hospitals and dispensaries 1,423 cases of *diarrhoea and enteritis* were treated. 876 of the cases occurring among children under 2 years of age.

Notified cases of *tuberculosis* (all forms) numbered 38 and of these 32 were cases of the *pulmonary* form of the disease—all the 27 deaths

ascribed to the disease were from pulmonary tuberculosis. To the Tuberculosis Sanatorium 8 female patients were admitted and 2 died. Other respiratory affections treated during the year included 2 776 cases of bronchitis (31 deaths) and 55 cases of pneumonia (40 deaths). Six out of 18 specimens of sputum examined were positive with *Mycobacterium tuberculosis*.

Cerebral Diseases—For syphilis 81 persons received treatment as hospital in patients while 461 patients were treated at the dispensaries etc. Gonorrhoea and its complications was responsible for 53 hospital in patient cases and 706 cases received dispensary treatment.

The incidence of yaws appears to be decreasing steadily during the year 5 117 new cases were seen while out of 9 874 cases treated 3 751 were discharged as clinically cured.

No mention is made in the text of the Report to the incidence of helminthic diseases but it is noted that no fewer than 10 515 cases of ascariasis were treated. Mortality was high for 52 deaths were certified under this title. Hospital in patients treated for ascariasis numbered 8 and for ankylostomiasis 5 (see this Bulletin 1938 Supp. p. 273*).

Other diseases treated during the year included the following—
Influenza was prevalent throughout the year. 2 181 cases were recorded with 9 deaths. Tetanus was responsible for 13 cases and 6 deaths. Whooping cough for 93 and measles for 8 non fatal cases.

Once again attention is called to the fact that there is a lack of agreement between statements made in different parts of the Report (see this Bulletin 1938 Supp. pp. 272*-273*). In addition to the examples given in the preceding notes the following may be mentioned—

Page 5 pneumonia 55 cases 40 deaths. Table 4 41 cases 25 deaths.
tuberculosis 38 cases 27 deaths. Table 5 32 cases.

6 23 deaths ascribed to syphilis. Table 4 gives 17 deaths.
5 8,874 cases of yaws treated. Table 4 mentions 5,357.

Scientific—The new Bacteriological Laboratory (see this Bulletin 38 Supp. p. 271*) was brought into use in May 1937 and from then the end of the year 437 specimens of various kinds were dealt with.

Financial—Total expenditure on Medical and Sanitary Services for 1937 amounted to £17 095 a sum which represents 18 per cent. of the total revenue of the Colony for the same year.

TRINIDAD AND TOBAGO (1937)

Trinidad (area 1 864 sq. miles) is the most southerly of the West Indian Islands lying about 16 miles off the coast of Venezuela in latitude 10° N. Tobago (area 118 sq. miles) is some 21 miles north-east of Trinidad.

Vital Statistics—The relevant facts supplied by the Registrar-General are as follows—

Estimated Population 31st Dec 1937	Registered Births	Birth Rate	Registered Deaths	Death Rate	Infant Mortality Rate
456 043	14,226	31.5	7 843	17.4	120.5

[Of the total population 154 083 were East Indians. The East Indian birth rate was 40.9 and the death rate 19.3 per 1 000.]

Maternity and Child Welfare Work.—At the *Colonial Hospital Port-of-Spain* 1,331 new cases attended the ante-natal clinic and recorded 6,214 attendances. Total admissions to the maternity section numbered 928 and of these 702 were normal confinements. 428 cases were delivered in the district by the hospital nursing staff. At the *Colonial Hospital San Fernando* 601 new cases attended the ante-natal clinic and recorded 1,952 attendances. Cases admitted to the maternity section numbered 435 and in addition 63 cases were delivered in the districts. The *Colonial Hospital Tobago* records 185 admissions to the maternity section and of these 148 were normal confinements.

Eight candidates from the Colonial Hospital, Port-of-Spain and 3 from the Colonial Hospital, San Fernando were successful in passing the *Midwifery Examination*.

Child Welfare Work continued to be carried out at the 14 district branches and 20 clinic centres maintained by the Child Welfare League (see this *Bulletin* 1933, Supp. p 274*).

School Hygiene.—The appointment of two School Medical Officers, one for the northern and one for the southern division, led to a new scheme of medical inspection, and a considerable extension of school medical services. It is hoped, with the assistance of District Medical Officers, to provide for the medical inspection of all school-children in the Colony. The new scheme provides for the examination of children in each school in four age-groups and for their examination at least three times during their school life. The year's work is set out in great detail: a brief summary reads as follows. In the *Northern Division* 29 schools visited, 4 178 children examined, 3 178 found with defects. In the *Southern Division* 22 schools visited, 3 142 children examined, 2,806 with defects. The principal defects noted were, carious teeth, malnutrition enlarged spleens, glands and tonsils, skin diseases. The large percentage of children exhibiting various defects suggests that some measure of control of the child of pre-school age (2-5 years) is necessary.

Public Health Sanitation, etc.—In order to meet the requirements of the reorganized service (see this *Bulletin* 1936 Supp. p 253* 1937 Supp. pp 268-269* and 1938, Supp. p 275*) a number of additional appointments to the staff of the Health Department were made during the year: these are referred to in various sections of this Summary.

Considerable attention continued to be devoted to anti-malarial work. It is said that data are now becoming available showing the monthly incidence of malaria in each district of the Southern Division. In addition to the usual routine measures undertaken, special works included the regrading and filling of low-level areas clearing and drainage works drain constructions and anopheline surveys.

For all practical purposes methods of *sewage disposal* remain unchanged. It is noted that a survey was completed during the year having in view the installation of a water-borne sewage system for the town of San Fernando and that on oil fields and estates water sewage systems are generally being adopted. During the civil disturbances in June 1937 when such essential health services as the emptying of

buckets and cesspits etc. were temporarily at a standstill in many places hospitals and institutions were unaffected and where water borne systems were installed on oil fields and estates, these functioned with complete satisfaction

The further extension of *water supplies* from the Central Water Supply Scheme was undoubtedly effective in preventing epidemic outbreaks during an abnormally long dry season in 1937. A large number of new areas in the Northern Division were served during the year but fewer in the Southern Division where there still remain areas drawing their supplies from sources considered inadequate and unsafe.

The *housing problem* has been a preoccupation of the Health Department for a number of years and while the difficulties associated with rural housing have rendered progress necessarily slow appreciable advance is reported in certain areas. The Report supplies a series of photographs typifying insanitary houses and barracks formerly existing and the new types which are gradually replacing them. Model villages were laid out in nine areas and others are envisaged. The appointment of a *Town Planning Adviser* was made towards the end of the year to meet the need for the systematic planning both of urban and rural areas (see also this *Bulletin* 1938 Supp. p 275*)

Under the heading of *labour conditions* the disturbances of June 1937 are mentioned their effects upon public health services the casualties dealt with and the sanitary conditions of the various military camps which had to be established.

The usual inspections and control of *foodstuffs* in shops and markets were satisfactorily carried out by the Sanitary Inspectors. Preliminary work on the determination of the *diets* of the people indicates a general lack of vitamins and first-class proteins but though early malnutrition states exist evidence does not point to widespread establishment of deficiency diseases (see this *Bulletin* 1938 Supp. p 275*)

The usual measures were taken to spread a knowledge of *hygiene and sanitation* among all classes of the community.

Port Health Work—No change was made in existing arrangements for the performance of duties concerned with maritime or aerial traffic (see this *Bulletin* 1938 Supp. p 276*) The following statement summarizes the year's work —

Ships Arriving	Ships Visited	Passengers and Crews	Persons Inspected	Persons under surveillance	Persons Vaccinated
353 Steam 879 Sall	342 878	21 348 4 657	21 348 } 4 657 }	240 (Smallport)	851

Hospitals Dispensaries etc—Attention is again called to the serious overcrowding in the Colony hospitals. The Colonial Hospital Port-of-Spain is equipped with 403 beds but the daily average number of patients was 422, while at the San Fernando Hospital of 194 beds the daily average of patients numbered 235. To relieve conditions expansion of Out patient Dispensaries was effected to permit of earlier discharges from hospitals of cases suitable for outside treatment.

Two new ward blocks capable of accommodating 96 patients approach completion at the Colonial Hospital, Port-of-Spain and various minor works were carried out at the hospitals at San Fernando Tobago and Princes Town. Other work to be undertaken includes additions to the Nurses Home and construction of a general administrative casualty block at the Port-of-Spain Hospital.

The facilities available for the isolation of cases of infectious diseases are inadequate and unsatisfactory and requirements can only be met by the provision of an Isolation Hospital with a trained nursing staff.

Two Ward Sisters and 14 Nurses were appointed during the year for service in the Colonial and District Hospitals.

A new syllabus of work was drafted for use in the three Nurses Training Schools in Port-of-Spain, San Fernando and Tobago with a view to securing uniformity of training and examination standards. The following successes were recorded at the annual examination for nursing certificates —

	1st year	2nd year	3rd year
Colonial Hospital Training School, Port-of-Spain	15	7	7
San Fernando	8	7	12

In the following Table are summarized details as regards bed accommodation and the volume of work dealt with in the various hospitals in the Colony during 1937 —

Institutions	Beds	Admitted	Treated	Died
<i>Colonial Hospitals —</i>				
Port-of-Spain	403	9 049	9 478	1 067
San Fernando	194	6 438	6 680	632
Tobago	78	1 467	1,525	90
<i>Six District Hospitals</i>	227	4 818	4,883	428
Mental Hospital	636	282	1 000	112
Lepet Asylum	400	78	458	29
House of Refuge Trinidad	700	456	1,044	259
Tobago	50	33	82	20
Three Emergency Hospitals	14	?	223	?

At the Ophthalmic Clinics of the Colonial Hospitals in Port-of-Spain and San Fernando 2,683 cases were treated. Large numbers of patients were treated at the Out-patient Departments and special clinics attached to all Hospitals. In addition at the 78 Health Offices (Dispensaries) established in the 18 Medical Districts of Trinidad 168,210 patients, and at the 16 dispensaries in the three Medical Districts of Tobago 7 686 patients were dealt with.

In spite of the occurrence of epidemics the general health of the Colony during 1937 is reported to have been satisfactory. The text of the Report under review discusses at varying lengths the principal items of morbidity and from these commentaries the following summaries have been prepared.

There was the usual seasonal incidence of *malaria* but the number of cases, 18,518, was less than in 1936. The disease is not notifiable

and the figures are necessarily incomplete. Microscopical diagnosis is not possible in many cases but among the 1,323 hospital in-patients treated during the year 577 were *benign tertian*, 4 *quartan*, 215 *subtertian*, 12 *malarial cachexia*, 8 were cases of *blackwater fever* and in 507 cases the nature of the parasite was not determined. [In the section discussing *malaria* on p. 15 of the Report under review a gross error characterizes the statement of admissions and deaths from malaria. The figures quoted relate to admissions and deaths due to all causes.]

At the Laboratory where 1,570 blood films were examined 324 contained malaria parasites and of the positives 267 were *P. falciparum* (16 with crescents), 51 *P. vivax* and 3 *P. malariae*.

No case of *yellow fever* or *smallpox* was reported and *smallpox* vaccination was continued.

Reported cases of *influenza* numbered 3,263 and 95 deaths were ascribed to this cause. The disease is not notifiable therefore the figures are incomplete. Incidence was highest from October to December when the number of cases constituted a small epidemic. The distribution of cases in Trinidad was Northern Division 1,307 Southern Division 1,699 and Tobago 257.

An outbreak of a mild type of *anterior poliomyelitis* occurred at the beginning of the year and continued to May. The disease had been reported from Venezuela towards the end of 1936 (4 cases occurred in Trinidad between September and December 1936) and it is possible that the infection was imported for there is a continuous interchange of persons and cargo between Venezuela and Trinidad. On the other hand it is to be remembered that a few cases occur each year in Trinidad during the wet season. During 1937 there were reported 102 cases and 6 deaths. The larger towns were chiefly affected but before the outbreak died out cases had occurred in all districts. 53 cases were reported from northern districts of Trinidad, 47 from the southern districts and 2 from Tobago. Over 80 per cent. of the patients were in the 0-5 age group. The epidemic is described at length in the Report under review.

Two outbreaks of *enteric fever* occurred during the year, one at Roxborough in Tobago in the early months of 1937 and the other at San Juan Trinidad in July-September, altogether 665 cases. Forty-three per cent. of these were children aged 5-15 years and 116 deaths were notified. The Roxborough epidemic gave rise to 76 cases of a mild type and as in other epidemics the victims were principally children of school age. Seventy-nine cases with 6 deaths resulted from the San Juan outbreak, and altogether 330 cases were reported from the Northern Division of Trinidad. The primary cases were children and infection was traced to bathing, drinking and washing in the San Juan river. At the Laboratory 1,603 samples of blood serum were submitted to the *Widal* tests and 410 agglutinated *Bact. typhosum*. Three typical clinical cases failed to give positive *Widal* reactions—yet in two *Bact. typhosum* was isolated from the faeces and in a third fatal case post-mortem revealed typical typhoid ulcers.

Dysentery was responsible for 396 cases and 95 deaths. Differentiation of types of infection was carried out only for the 173 cases (35 deaths) treated as hospital in-patients. Of these 153 were *amoebic*, 13 *bacillary* and in the remaining 27 cases the type of infection was

Two new ward blocks capable of accommodating 96 patients approach completion at the Colonial Hospital, Port-of Spain and various minor works were carried out at the hospitals at San Fernando Tobago and Princes Town. Other work to be undertaken includes additions to the Nurses Home and construction of a general administrative casualty block at the Port-of Spain Hospital.

The facilities available for the isolation of cases of infectious diseases are inadequate and unsatisfactory and requirements can only be met by the provision of an Isolation Hospital with a trained nursing staff.

Two Ward Sisters and 14 Nurses were appointed during the year for service in the Colonial and District Hospitals.

A new syllabus of work was drafted for use in the three Nurses Training Schools in Port-of Spain, San Fernando and Tobago with a view to securing uniformity of training and examination standards. The following successes were recorded at the annual examination for nursing certificates —

	1st year	2nd year	3rd year
Colonial Hospital Training School Port-of Spain	16	7	7
San Fernando	8	7	12

In the following Table are summarized details as regards bed accommodation and the volume of work dealt with in the various hospitals in the Colony during 1937 —

Institution	Beds	Admitted	Treated	Died
<i>Colonial Hospitals —</i>				
Port-of Spain	403	9 049	9 478	1 067
San Fernando	184	6 438	6 860	632
Tobago	78	1 467	1 525	99
<i>Six District Hospitals</i>	227	4,816	4,858	428
Mental Hospital	636	262	1 009	112
Leprosy Asylum	400	78	488	29
House of Refuge Trinidad	700	456	1,044	256
Tobago	50	33	82	20
Three Emergency Hospitals	14	?	223	?

At the Ophthalmic Clinics of the Colonial Hospitals in Port-of Spain and San Fernando 2,683 cases were treated. Large numbers of patients were treated at the Out-patient Departments and special clinics attached to all Hospitals. In addition at the 78 Health Offices (Dispensaries) established in the 16 Medical Districts of Trinidad 168,210 patients and at the 16 dispensaries in the three Medical Districts of Tobago 7 688 patients were dealt with.

In spite of the occurrence of epidemics the general health of the Colony during 1937 is reported to have been satisfactory. The text of the Report under review discusses at varying lengths the principal items of morbidity and from these commentaries the following summaries have been prepared.

There was the usual seasonal incidence of malaria but the number of cases, 18,518 was less than in 1936. The disease is not notifiable

and the figures are necessarily incomplete. Microscopical diagnosis is not possible in many cases but among the 1,323 hospital in-patient cases treated during the year 577 were *benign tertian*, 4 *quartan*, 215 *subtertian*, 12 *malarial cachexia*, 8 were cases of *blackwater fever* and in 507 cases the nature of the parasite was not determined. [In the section discussing *malaria* on p. 15 of the Report under review a gross error characterizes the statement of admissions and deaths from *malaria*. The figures quoted relate to admissions and deaths due to all causes.]

At the Laboratory where 1,570 blood films were examined 324 contained *malaria* parasites and of the positives 267 were *P. falciparum* (16 with crescents), 54 *P. vivax* and 3 *P. malariae*.

No case of *yellow fever* or *smallpox* was reported. *anti-smallpox* vaccination was continued.

Reported cases of *influenza* numbered 3,263 and 95 deaths were ascribed to this cause. The disease is not notifiable therefore the figures are incomplete. Incidence was highest from October to December when the number of cases constituted a small epidemic. The distribution of cases in *Trinidad* was Northern Division 1,307 Southern Division 1,699 and *Tobago* 257.

An outbreak of a mild type of *anterior poliomyelitis* occurred at the beginning of the year and continued to May. The disease had been reported from *Venezuela* towards the end of 1936 (4 cases occurred in *Trinidad* between September and December 1936) and it is possible that the infection was imported for there is a continuous interchange of persons and cargo between *Venezuela* and *Trinidad*. On the other hand it is to be remembered that a few cases occur each year in *Trinidad* during the wet season. During 1937 there were reported 102 cases and 6 deaths. The larger towns were chiefly affected but before the outbreak died out cases had occurred in all districts. 53 cases were reported from northern districts of *Trinidad*, 47 from the southern districts and 2 from *Tobago*. Over 80 per cent. of the patients were in the 0-5 age group. The epidemic is described at length in the Report under review.

Two outbreaks of *enteric fever* occurred during the year, one at *Roxborough* in *Tobago* in the early months of 1937 and the other at *San Juan*, *Trinidad*, in July-September, altogether 665 cases. Forty three per cent. of these were children aged 5-15 years and 116 deaths were notified. The *Roxborough* epidemic gave rise to 76 cases of a mild type and as in other epidemics the victims were principally children of school age. Seventy-nine cases with 6 deaths resulted from the *San Juan* outbreak and altogether 330 cases were reported from the Northern Division of *Trinidad*. The primary cases were children and infection was traced to bathing, drinking and washing in the *San Juan* river. At the Laboratory 1,603 samples of blood serum were submitted to the *Widal* tests and 410 agglutinated *Bact. typhosum*. Three typical clinical cases failed to give positive *Widal* reactions—yet in two *Bact. typhosum* was isolated from the faeces and in a third fatal case post mortem revealed typical typhoid ulcers.

Dysentery was responsible for 396 cases and 95 deaths. Differentiation of types of infection was carried out only for the 173 cases (35 deaths) treated as hospital in-patients. Of these 153 were *amoebic*, 13 *bacillary* and in the remaining 27 cases the type of infection was

- A study in syphilis. The causation of ophthalmic disorders in coloured races with special reference to the British West Indies. *British Journal of Venereal Diseases* 1937 October.

Financial—In accordance with usual practice the financial statement is presented with considerable detail. Total expenditure on Health Department services amounted to \$1 051,601 a sum which represents 9.8 per cent. of the total expenditure of the Colony during 1937.

SOUTH ATLANTIC

FALKLAND ISLANDS (1937)

The Falkland Islands are situated in the South Atlantic Ocean between 51° and 53°S latitude and 57° and 62°W longitude some 480 miles N.E. of Cape Horn and 1 000 miles due south of Monte Video. They consist of East Falkland (area 2,550 sq miles) and West Falkland (2,038 sq miles). There are two groups of dependencies: (1) South Georgia with South Orkney and South Sandwich and (2) South Shetland and Graham Land. South Georgia lies about 800 miles to the east of the Falkland Islands and South Orkney and South Sandwich some 450 miles to the south-east and south-west respectively of South Georgia. South Shetland is 500 miles south of the Falklands.

Vital Statistics—The estimated population of the Falkland Islands at the end of the year was 2 391. Registered births numbered 37 and deaths 20, the resulting birth and death rates being 15.5 and 8.4 respectively. For the Dependencies (see above) the corresponding data reads: population 700, births one, deaths nil.

It is interesting to note that in the Island of East Falkland where approximately 65 per cent. of the total population are to be found there were no infant deaths recorded. In West Falkland there were two such deaths.

Maternity and Child Welfare Work—At the King Edward VII Memorial Hospital Stanley special arrangements are made for dealing with ante-natal cases. The general physical examination made at first visits is followed by examinations at fortnightly and monthly intervals. During the year 25 women were on the registers of the Ante-natal Clinic and were seen in the aggregate 81 times. Of the 30 women delivered at the Hospital only 3 appear to have had no ante-natal supervision. At the *Infant Welfare Clinic* which is held at weekly intervals during the first year of life infants are seen first at intervals of two weeks and later every month. During the second year they are seen at two-monthly intervals. The aggregate attendance was 470 with an average attendance of nine.

School Hygiene—The pupils at the Government and St. Mary's Schools were examined. Pupils are examined in the presence of their parents and defects etc. discussed at the time. Dr G. KINYEARD refers to the adoption of the *Vau Pirquet Pelidisi* scale† used for the assessment of nutrition of pupils during 1936 (see this *Bulletin* 1938 Supp. p. 283*) which declared that 82 pupils then examined were under-nourished. Re-examination of these children showed that on a

† *Vau Pirquet Pelidisi scale*—the index formed by taking the cube root of ten times the weight of the subject in grammes divided by the sitting height in centimetres and multiplying by 100. *Vau Pirquet* found in Vienna that a healthy child had an index of 100.

This index was first called "*Gedulss*" from the first syllables of the words forming the sentence: *Gewicht zehnfach linear durchziehen der dritten Wurzel, dividiert durch Sitzhöhe*. Subsequently the word "*Pelidisi*" was preferred, derived from the Latin: *Pondus decies lineare divisio sedentis altitudo*.

See *Guiding Principles for Studies on the Nutrition of Populations* by E. J. Bigwood. Published by the League of Nations Health Organisation, Geneva, 1939. Footnote, p. 168.

clinical basis only 50 children were under nourished. Among other findings recorded it is stated that 36 per cent. of the children examined had dental caries 31 per cent. some abnormality of nose or throat and 8 per cent. some eye defect.

It is pointed out that Section 13 of the Education Ordinance requires the Government Medical Officer to examine school-children at least once a year though he is not specifically enjoined to pay any attention to the subject of school hygiene. In the opinion of Dr Kinneard the Education Ordinance requires amendment in order to provide the Senior Medical Officer or Board of Health with authority to insist that prescribed hygiene standards shall be maintained in all schools.

Public Health, Sanitation etc.—In February 1937 Dr G Kinneard succeeded Dr R. L. Cheverton as Senior Medical Officer of the Falkland Islands. During the year under review the Health of the Colony showed no unusual or disquieting features. The *Public Health Ordinance* No. 5 of 1894 was amended provision was made for the creation of a *Board of Health* for the whole Colony for regulations empowering any Inspector of Nuisances to enter premises used for the sale of butcher's meat and for the punishment of persons exposing for sale meat unfit for human consumption, and regulations for the proper control of markets and slaughter-houses.

Dr Kinneard describes the somewhat unusual system of sanitation and general hygiene in the Town of Stanley. The Senior Medical Officer is responsible for the health of the Colony as a whole and sits as President of the Board of Health. The Director of Public Works has a seat on the Board of Health though is independent of it as regards all questions of sanitary engineering, and is in control of the hygiene of public buildings, public baths schools *sewage* and *refuse* and *water supplies*. Of the 284 houses in Stanley 218 have connections to the main sewer and 168 have piped water supplies. A few houses still use rain water and the pail system of night soil disposal is in use in houses not connected to the main sewer. All new houses are required to be connected to main water and sewage systems. The Board of Health is empowered to condemn and demolish houses unfit for human habitation.

Medical service outside Stanley is provided on the public health side by Government. As regards medical care the Falkland Islands Company maintains a resident doctor at Darwin who attends to people in the Company's Camp and in two other stations. Patients requiring hospitalization are admitted to the King Edward VII Memorial Hospital. One Government Medical Officer is constantly maintained on the West Falkland and one in Stanley to assist the Senior Medical Officer and to attend non-Company stations. Medical Officers tour all camp stations twice a year.

As regards the *nutrition* of the population in the Falklands (see this *Bulletin* 1938 Supp. p. 283*) a Committee was appointed by His Excellency the Governor in 1936 and their *Memorandum on Nutrition* which was submitted in 1937 is presented as an Appendix to the Report under review. This *Memorandum* discusses the problem under the following headings, (I) Present knowledge of nutrition in the Colony (II) Practical measures taken in the past to apply scientific knowledge to the improvement of nutrition, (III) Measures studies and researches in connexion with nutrition which appear

desirable in this Colony and (IV) Consequences which improvement in nutrition would have on the economy of the Falklands.

Health Education during the year took the form of lecture demonstrations on food the writing of essays on health subjects by school children the holding of a Baby Show and individual teaching at the various Clinics.

Port Health Work—Relatively few ships from foreign ports enter the Colony of the 26 ships entering Port Stanley during the year 13 were from Monte Video and 8 from Chile. Arrangements have been made with H B M Consuls in various South American ports to wireless information in the event of any scheduled infectious disease occurring at such ports. Regular written reports are also received covering the incidence of communicable diseases in Monte Video the latter port is the principal point of contact—mails are carried to and from Monte Video by local vessels and mail communication with the United Kingdom thus ensured. During 1937 all vessels approaching the Colony were requested to send a radio message to the Senior Medical Officer if they had a clean Bill of Health etc. This method of arranging radio-pratique appears to have functioned successfully.

Hospitals Dispensaries etc—Admissions to the King Edward VII Memorial Hospital numbered 219 and 6 deaths were recorded. New cases amongst out patients numbered 1010 and subsequent visits for treatment 2084. In the District 296 first visits of out patients were recorded and 652 subsequent visits.

Difficulty was experienced in securing *nurse probationers* the regulations are being revised with a view to providing more attractive terms.

The Medical Officer West Falkland reports that during the year 302 cases were seen of these 183 were dealt with at Headquarters and the remainder at the various stations (there are 12 such centres) entailing an absence of 50 nights from Headquarters.

No Government Doctor is stationed in the Dependencies medical services being rendered by ships surgeons on whaling ships no details are supplied.

The Report of the Dental Surgeon is presented as an Appendix to the Report under review. Work was begun to determine (a) the average caries rates for various age-groups (b) the structure and quality of teeth, (c) the effect (if any) upon the teeth of a group of children of administering a pint of milk and fifteen drops of Radiostoleum daily for one year (d) any marked difference between the average Falkland Island diet and a balanced ideal diet and (e) any marked difference in the dental caries rate experienced by the foreigner in the Falklands and during residence elsewhere.

As regards *morbidity experience* it is noted that 1937 was completely free from most if not all the communicable diseases. No case of measles scarlet fever diphtheria whooping cough enteric fever or meningitis was seen.

Six cases of *tuberculosis* were recorded. The Agricultural Adviser carried out over 100 tuberculin tests on cattle but found no reactors. Other diseases of the *respiratory system* were responsible for 12 in-patient admissions, 101 cases treated as hospital out patients and 45 district out patients.

In July an epidemic of *influenza* swept the Colony there was no mortality from *influenza* proper but several cases of broncho-pneumonia associated with attacks of *influenza* terminated fatally. Hospital returns show that 6 in-patients were treated for the diseases there were 24 Hospital and 96 District out patients. In the West Falklands 72 cases were recorded and in the Dependencies 14.

Dr. Kinneard supplies a brief but interesting commentary on various epidemiological aspects of the outbreak. A crude attack rate of 67 per cent. was distributed as to 65 per cent. in the 5-15 age-group 72 per cent. in the 16-40 age-group and 64 per cent. at ages over 40.

During the warmer months simple cases of *diarrhoea* and *enteritis* were observed. At the King Edward VII Memorial Hospital 6 in patients were admitted for *enteritis* among hospital and district out patients 44 were treated for *diarrhoea* and 47 for *dyspepsia* (see this *Bulletin* 1938 Supp. p. 284*). The Medical Officer West Falkland, treated 79 patients for *diseases of the digestive system*.

Infectious adenitis or *glandular fever* is said to have been observed in several children. One case at the King Edward VII Memorial Hospital and one in West Falkland are recorded. *Impetigo* was frequently seen among out patients. A particularly virulent form developed almost epidemic proportions in West Falkland, and proved resistant to treatment.

Considering the size of the population, *diabetes* and *asthma* are said to be unusually prevalent. A considerable decrease in the numbers of cases of *appendicitis* is noted. 22 cases are shown in the classified returns 12 were treated as in patients, and only 11 appendicectomies were performed as compared with 40 in the preceding year (see this *Bulletin* 1938 Supp. p. 284*).

In the 1936 Report investigation of the *haemorrhagic diathesis* which appeared to characterize the members of certain family groups in the Falklands was suggested. Dr. Kinneard is of the opinion that in view of the many technical difficulties involved, the attempt to carry out such an enquiry might be postponed for the present. no cases of abnormal bleeding were encountered during the year.

The Report observes venereal disease is very seldom seen. Only two proved cases of *gonorrhoea* (both in seamen) and one suspected tertiary syphilitic were treated during the year.

Financial—Total expenditure on Medical and Sanitary services during 1937 amounted to £5 015 (the figure given in the 1936 Report, excluding the item Personal Emoluments) a sum which represents 7 per cent. of the total revenue of the Colony over the same period.
